AND ASHER, BERLIN.
1905.
"Onnes res creatse sunt divina sapientixet potentia testes, divitix felicitatis humane: - ex harum usubonites Creatoris; ex pulchritudine sapientio Domini ; ex aconomiat in conservatione, proportione, renovatione, potentia majestatis elucet. Earum itaque indagatio ab hominibus sibi relictis semper astinata; à rerè eruditis et sapientibus semper exculta; malè doctis et barbaris semper inimica fuit."-Linneus.
"Quel que soit le principe de la vie animale, il ne faut qu'ourrir les yenx pour roir qu'elle est le chef-d'curre de la Toute-puissance, et le but auquel se rapportent toutes ses opérations."-Bruckner, Théorie du Système Auimal, Leyilen, 1767 .
. . . . . . . . . . . The sylvan powers
Obey our summons; from their deepest dells The Dryads come, and throw their garlands wild And odorous branches at our feet; the Nymphs That press with nimble step the mountain-thyme And purple heath-flower come not empty-handed, But seatter round ten thousand forms minute Of relvet moss or lichen, torn from rock
Or rifted oak or cavern deep: the Naiads too Quit their loved native stream, from whose smooth face Thes crop the lily, and each sedge and rush That drinks the rippling tide: the frozen poles, Where peril waits the bold adventurer's tread, The burning sands of Borneo and Cayenne, All, all to us unlock their seeret stores
And pay their cheerful tribute. J. Taylor, Norvich, 1818.

No. 85. JANUARY 1905.
I.-Notes on some Recent Bryozoa in d'Orbigny's Collection. By Arthur Wm. Waters.
[Plate I.]
Before completing my memoir * on the Bryozoa collected in the Antarctic by the 'Belgica,' I looked through d'Orbigny's collection to see if it contained any of the species found in the Antarctic. These recent $\dagger$ Bryozoa are in the Palæontological Department of the Muséum d'Histoire naturelle in Paris, and were referred to by d'Orbigny in the 'Paléontologie Française,' Terrains C'rétacés, vol. v., and some had already been described by him in 'Voyage dans l'Amérique Méridionale.' However, a large proportion of the species

[^0]were described in such a way that we have had no idea as to the species intended, for the characters used were not those which we now know are of most importance.

Although my examination was but a very hurried one, it was possible to recognize many species which havesince d'Orbigny's time been more fully described; in others the affinities only could be indicated, for it is often only possible to make a determination after prolonged examination and preparation of opercula and other structures, besides reference to the literature. Some of the most important books were at my side during the examination, but it was not possible to have all available as if I had worked in my own study. In some cases nothing more could be said than that the determination of some unsatisfactory specimens is impossible; but even this may save other people time and prevent their trying to make impracticable comparisons and determinations.

Naturally our knowledge of the geographical distribution is increased in many cases, and some of the 'Challenger' species had been previously seen by d'Orbigny, as :-

Thalamoporella labiata, Busk. Adeonella polymorpha, Busk. Lepralia japonica, Busk.

> Haswellia auriculata, Busk. Adeonella platalea, Busk.

It has seemed advisable to refer to the species in the order in which they occur in the 'Paléontologie Française,' giving the page and plates, when figured, then the reference to 'Voyage dans l'Amérique Méridionale' is added, as well as to my memoir of the Bryozoa from the Antarctic collected by the 'Belgica,' and to a paper of mine on Bryozoa from Cape Horn now in the printer's hands. It may be taken that, with few exceptions, the names in the collection are those given in the 'Paléontologie Française,' but a few species have the names given in the 'Voyage,' and some others the convenient name Cellepora; but it has not been necessary to refer to these exceptions.

It will be understood that only a part of the recent Bryozoa described by d'Orbigny are here mentioned and that the paper is worked up from rough notes made during a short visit. Fig. 1 (Pl. I.) is drawn from the actual specimen, but the other figures are drawn from rough sketches and must be considered to a large extent diagrammatic.

[^1]

| 粡 |
| :---: |

| 443 | ... | 13674 | Reptoporina cormuta, d Orb. <br> Escharina cormuta, d'Orb. Voy. Amer. | Chili. I do not find any $R$. cornuta on the shell. There is, however, Smittic Alvareaiana, d'Orb. |
| :---: | :---: | :---: | :---: | :---: |
| 4.4 | . . $\cdot$ | 13677 | Teptoporina aspera, d'Orb. | Algiers. =Schizoporella with small round avicularium below the oral aperture. |
| 444 |  | 13078 | Reptoporina candeana, d'Orb. | Chinese Seas. =Schizoporella with round avicularium below the sinus, wide globular ovicell. |
| 447 | $\begin{gathered} 714, \\ \text { figs. } 1416 \end{gathered}$ | 13679 | Conescharellina angustata, d Orb. | lle de Basilan. (Pl. I. fig. 7.) D'Orbigny's figure does not give a correct idea. The zoocia occur in longitudinal rows, and between these rows there is a depressed groove with avicularian or vibracular pores. The zoocin have an oval aperture with an avicularium below it. |
| 447 | $\cdots$ | 13680 | Conescharellina dilatata, $\mathrm{d}^{\prime} \mathrm{Orb}$. | Manila. (Pl. I. fig, 6.) There are two species in the tube. One has a nearly round oral aperture, with an avicularium below, and between the rows of zoocia there is a depressed groove with a single row of large pores. |
| 45.3 | ... | 13686 | Reptescharellina Alvareziana, d'Orb. Escharina Alvareziana, d'Orb. Voy. <br> Amér. Mér. p. 14, pl. vi. figs. 1-4. <br> Smittia Alvarezaana, Waters," Bry. Cape IIorn," Journ. Linn. Soc., 'Zool. | Payta (Peru). The figure is protty good, but the avicularia project further out than figured. No ovicells. Small mucro to aperture. |
| 454 |  | 13689 | Reptescharellina borealis, d'Orb. | Newfoundland. = Schizoporella vulgaris, Moll. |
| 453 | .... | 13688 | Reptescharellina armata, d'Orb. Eischarina armata, d'Orb. Voy. Amér. Mér. p. 15, pl. vii. figs. 5-8. | Falkland Islands. = Microporella ciliuta. There is $\Omega$ crescentic pore, granulated surface, avicularium at one side. |
| 4.5:3 | . . . | 13687 | Reptescharellina regularis, d'Orb. Lischarina reqularis, d'Orb. Voy. Amér. Mér. p. 15, pl. vi. figs. 13-16. | Payta. This is Microporella, probably M. ciliata, var. californica, Hincks. |
| 4.51 |  | 13690 | Reptescharellina incequalis, d'Orb. | Malacca. (Pl. I. fig. 8.) =Schizoporella. Zoœcial surface granular, pores round the border of the zoocium; on one or both sides of the oral aperture an avicularium on a raised chamber directed downwards, and an oval avicularium immediately below the siuus placed |

| 465 |  |  | Reptescharella rimulata, MacG. Escharina rimulata, d'Orb. Voy. Amér. Mér. p. 15, pl. vii. figs. 1-4. | tubes. In Lepralia Poissonii, Aud., there are delicate spines round the border of the zoocium, and the function may be similar. The primary zoocium, as seen from below, is nearly round. <br> Falkland Islands. In the tube there is a ticket, "échantillons manquant"; but the Smittia reticulata, Mact., occurs on other shells, and we may take it that d'Orbigny had S. reticulata before him. |
| :---: | :---: | :---: | :---: | :---: |
| 466 | ... | 13696 | Reptescharella indica, d'Orb. | Straits of Malacca. It is Cribrilina, probably radiata without avicularia. |
| 474 |  | 13700 | Discoporella Berardana, d'Orb. | Algiers. $=$ ('upularia umbellata, Defr. |
| 477 |  | 13697 | Reptoporellina porosa, d'Orb. | Algiers. $=$ Microporella Ileckeli ${ }^{*}$, Reuss,$=$ M. violacea, auct. |
|  |  | 13097 A | Reptoporellina porosa, d'Orb. | Corsica. M. ILeckeli, Reuss. |
| 478 |  | 13698 | Reptoporellina costata, d'Orb. | Malacea. There are several species on the shell, but the one referred to will be Smittio reticulata, MacG. |
| 490 |  | 13699 | Repteschuripora complanata, d'Orb. | Manila. There are several species on the shells, but the one which I think was referred to by d'Orbigny is a Smittia much like $S$. reticulatu, var. spathulata, MacG. The oblong rectangular zoœcia grow in regular longitudinal lines; they are surrounded by a row of pores, and at one side there is a large curved avicularium. |
| 515 |  | 13704 | Flustrellaria candeana, d'Orb. | Malacca. = Membranipora Savartii, Aud., or allied species. |
| 539 |  | 13706 | Pyripora r'amosa, d'Orb. | Ile de Noirmoutiers. This has a long oval opesium and belongs to the Pyripora group of the Membraniporide. |
| 541 |  | 13707 | Membranipora echinata, d'Orb. Voy. Amér. Mér. p. 16, pl. vii. figs. 13-17 (misprinted in text eschinata). | Chili. On one specimen there were 7 spines, but another specimen so named was M. spinosa. |

[^2]| Pal. Franç. vol. v. |  | Number. | Name in Pal. Franç. | Locality and Remarks. |
| :---: | :---: | :---: | :---: | :---: |
| Page. | Plate. |  |  |  |
| 542 |  | 13708 | Membranipora spinosa, d'Orb. Voy. Amér. Mér. p. 16, pl. viii. tigs. 1-4. | L'eru. The specimen has no spines, and perhaps spongespicules were mistaken for spines: hot there is a Membranizora from Chili with 17-18 spines which is M. spinosa. |
| 542 |  | 13709 | Membranipora irregularis, d'Orb. Voy. Amér. Mér. p. 17, pl. viii. figs. $5,6$. | Peru. There is no Membranipora on the shell, only Microporella Malusii, Aud. |
| 542 |  | 13713 | Membramipora sinensis, d Orb. | Chinese Seas. (Pl. I. fig. 9.) It has a large round opesium, a small cap-like ovicell, and by the distal edge a long slightly curved avicularium. This reminds us of M. migrans, Hinclis, but the avicularia are much longer. |
| 543 | $\ldots$ | $\begin{gathered} 13714 \\ 1: 3714 \mathrm{~A} \end{gathered}$ | Membranipora malaccensis, d'Orb. Membranipora malaccensis, d'Orb. | Malacea. = M. Sarartii, Aud., group. <br> Ile de Galega. This is quite a different thing. |
| 543 | $\ldots$ | 13716 | Membranipora bipartita, d Orb. | Newfoundland. = Biflustra aculeata, d'Orb. Pal. Fr. p. 244 (see page 5). |
| 5.43 | . . . | 13715 | Membranipora ciliata, d'Orb. | Calvados. Someone had written in the box "spinifera." There are stout spines round the border, and it is probably M. spinifere, Johnst. |
| 561 | .... | 13718 | Discoflustrella doma, d'Orb. | Algiers. Kowcium hexagonal, with the oral aperture subtriangular. |
| 570 | $\ldots$ | 13722 | Pyriflustrella arctica, d'Orb. | Spitzbergen. = Microporello with large zoccia; surface coarsely granular, few small pores over the surface; median pore round, not far from the oral aperture. |
| 571 | ... | 13721 | Reptoflustrella americana, d'Orb. | Newfoundland. This is what Norman has called Callopora unicornis, var. armifera, Hincks (Ann. \& Mag. Nat. Hist. ser. 7, vol. xi. p. 591). |
| 582 | .... | 13724 | Reptoflustrina arctica, d'Orb. | Spitzbergen. = Membranipora with large oval opesium, a wide cap-like ovicell, with a small avicularium at each corner of the ovicell. |

| 816 | $\begin{gathered} 760, \\ \text { figs. } 7-9 \end{gathered}$ | 13770 | Berenicia prominens, Lamx. | Mediterranean. Some specimens are Diastopora obelia, Johnst, and others are a Diustopora without interzoocial tubules (zoociules), and in these the closure of the zooccia has tubules. |
| 890 |  | 13772 | Claviclausa africana, d'Orb. | Algiers. This is Entalophora with the ends of the branches clavate. |
| 894 |  | 13771 | Clausa rustica, d'Orb. <br> Pustulopora rustica, d’Orb. Voy. Amér. Mér. p. 23, pl. x. figs. 1315. Bifararia rustica, Waters, Exp. Ant. Belre, Bry. p. 60 , pl. viii. figs. $19 a, b$. | Falkland Islands. |
| 919 | $\ldots$ | 13778 | Hornera lichenoides, Pont. | Mediterranean. There is II. frondiculata, Lamx., and $^{\text {a }}$, another IIornera is either M. lichenoides, Pont., or II. mediterranea, Waters. |
| 972 |  | 13781 | Unicavea californica, d'Orb. | The zoncia are uniserial, slightly raised; zoocia and cancelli about the same size. This does not seem to be the Discoporella californica, Busk. |
| 972 | $\ldots$ | 13779 | Unicavea clypeiformis, d'Orb. Voy. Amér. Mér. p. 19, pl. ix. figs. 4-6. | Falkland Islands. 'This is of the Lichenopora hispida, Flem., group. The zoœcia are larger than the cancelli. |

Other species seen.
Monoporella albicans, Hincks, 13782, occurs from Cuba with Unicavea.
Nicroporella parvipora, Waters, 13676, Falkland Islands, with Stomatopora. Esp. Ant. Belge, p. 43, pl. iii. figs. $2 a, b$.
Smittia reticulata, MacG., 13676, Falkland Islands.
Eucratea amligua, d'Orb., 13672, Falkland Islands, with Tubulipora organisans, d'Orb.
Laminopora? contorta, d'Orb., locality not given. Michelin, Magasin de Zoologie, 1842, pl. iii. This does not seem to be uncommon in the North Atlantic, as unnamed specimens occur in several museums. Many of the characters resemble those of Schizoporella bimimita, Hincks. Busk marked a specimen now in the British Museum from John Adams Bank, Cape de Verde, "Herald," with the manuscript name Adeonella dolichostoma, Busk.
Smittia pavonella, Alder, occurs from Teneriffe.

II.-On a Collection of Fishes from the Inland Sea of Japan made by Mir. R. Gordon Smith. By C. 'Tate Regan, B.A.

[Plates II. \& III.]

The British Museum has recently received from Mr. R. Gordon Smith a large series of fishes collected by him in the Inland Sea of Japan, containing examples of thirteen species which appear to be new to science.

In the following list I have included the new species, with some which appear to be new to the Japanese fauna and others which it seems useful to notice or to redescribe.

## 1. Clupea zunasi, Bleek.

Guinther places this species in the section with toothless palate, but although the palate appears to lack teeth in the typical example preserved in the British Museum, several specimens collected by Mr. Gordon Smith have small teeth on the palate, as stated by Bleeker in his description of tho species.

## 2. Ophichthys internedius, sp. n.

Depth of body $2 \frac{2}{3}$ in the length of head, which is $3 \frac{1}{5}$ in the length of the trunk or $10 \frac{2}{3}$ in the total length of the fish. Length of tail $1 \frac{3}{5}$ that of head and trunk. Diameter of eye $1_{5}^{4}$ in the snout, which is $5 \frac{1}{2}$ in the length of head. Teeth pointed, in a single series in each jaw. Pectoral a little more than $\frac{1}{3}$ the length of head. Origin of dorsal above anterior $\frac{1}{4}$ of pectoral. Upper part of the body brown, with some yellow blotches or irregular bands; lower part of the body yellowish. Dorsal with alternate light grey and blackish blotches and with a blackish edge ; anal grey, black-edged; pectoral blackish.

A single specimen, 910 mm . in total length.
The genus Microdonophis, distinguished from Ophichthys by having the origin of the dorsal in front of the base of the pectoral instead of behind it, seems hardly worth recognition. The species described above approaches more nearly to Microdonophis in respect of this character than to most species of Ophichthys.

## 3. Belone annulata, Cuv. \& Val.

Previously recorded from China and various Indo-Pacific localities.

Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.

## 4. Exocotus Solandri, Cuv. \& Val.

Previously recorded from the Indian Ocean.
5. Ammodytes alascanus, Cope.

Previously recorded from Alaska.

## 6. Splyyrena pinguis, Günth.

Previously recorded from Chefoo.

## 7. Bregmaceros Macclellandi, Thomps.

Previously recorded from the Indian Ocean, China, and the Philippine Islands.

## 8. Caprodon Schlegelii, Günth.

Depth of body $2 \frac{3}{5}$ in the length, length of head $3 \frac{2}{5}$. Snout nearly as long as eye, the diameter of which is $3 \frac{2}{3}$ in the length of head. Maxillary extending to below posterior edge of pupil, the width of its distal extremity $\frac{2}{3}$ the diameter of eye. 24 gill-rakers on the lower part of anterior arch. Dorsal X 21, the spines increasing in length to the fourth, which is $\frac{2}{5}$ the length of head and nearly as long as the longest soft rays. Anal III 8. Pectoral $1 \frac{1}{3}$ the length of head; ventral shorter than the head, not extending to the anal. Caudal truncate. Scales $666_{24}^{6}$. Lateral line 62. Pink; two yellow stripes in front of the eye; fins yellowish; posterior part of spinous dorsal with an irregular blackish blotch.

Total length of the specimen described, 270 mm .
This species is principally distinguished from the South Pacific C. longimanus, Günth., by the wider mouth and the truncate caudal.

## 9. Chcetopterus Sieboldii, Bleek.

Body ovate, moderately compressed. Depth of body 24 in the length, length of head $3 \frac{3}{5}$. Snout shorter than eye, the diameter of which is $3 \ddagger$ in the length of head, interorbital width $2 \frac{2}{3}$. Mouth oblique ; jaws equal anteriorly ; maxillary exposed, without supplemental bone, extending to below anterior $\frac{1}{4}$ of eye, the width of its distal extremity $\frac{2}{5}$ the diameter of eye; promaxillaries protractile; small villiform teeth in bands in jaws and on vomer and palatines; both jaws with a moderately enlarged outer series of tecth and with 2 or 3 moderate canines on each side anteriorly. Præorbital
narrow. Interorbital region, snout, jaws, suborbitals, and preoperculum naked; rest of the head scaly. Cheek with 6 series of scales; preoperculum rounded and slightly produced at the angle, with radiating ridges and crenulate margin; operculum with two spines. Pseudobranchiæ well developed; gill-rakers as long as gill-fringes, 20 on the lower part of anterior arch; six branchiostegals. Dorsal X 10, the spines increasing in length to the fourth, which is nearly $\frac{1}{2}$ the length of head, the last a little more than $\frac{1}{3}$ the length of head. Anal III 8. Dorsal and anal fins scaleless. Pectoral falcate, with 17 rays, longer than the head, extending to above the origin of anal. Ventrals commencing a little behind the pectorals, extending to the vent. Caudal deeply forked, covered with scales except near the posterior margin. Scales finely denticulated, $72 \frac{\mathrm{~S}}{19}$. Lateral line concurrent with the dorsal profile. Uniformiy olivaceous.

Total length of the specimen described, 230 mm .
This species has been referred by Jordan and Suyder to the genus Aprion, Cuv. \& Val. I have compared it with the type species, $A$. virescens, which differs notably in the more elongate body, larger mouth and stronger dentition, deeper præorbital and very short pectoral. It is also evident that the structure of the skull must be very different. I have also compared C. Sieboldii with Aspilus dentatus, Guichenot, which is the type of the genus Tropidinius, Gill, but is placed by Messrs. Jordan and Evermann in Aspilus, Cav. \& Val. The two species appear to me to be closely allied and certainly congeneric. On the other hand, Aspilus fuscus, the typical species of the genus Aspilus, seems to be a very different fish, especially in lacking canine teeth. I am therefore inclined to retain the genus Chatopterus and to regard Tropidinius as a synonym of it.

## Gymnapogon, gen. nov.

Allied to Telescopias, Jord. \& Snyder. Body oblong, compressed; scales entirely wanting; sides of head with a network of series of small pores; body with 20 or more vertical series of small pores on each side, and with the lateral line apparently represented by a longitudinal series running to below the soft dorsal and usually commencing again on the middle of the side and running to the base of the caudal. Mouth wide, oblique; jaws equal anteriorly; maxillary exposed; teeth pointed, in a single series in tie jaws and on the palatines; vomer with a few tecth; lower jaw with 3 or 4 curved canines on each side, placed laterally;
upper jaw with 2 or 3 anterior canines on each side. Preoperculum entire, with a produced membranous flap at the angle. Gill-membranes not united; seven branchiostegals; gill-rakers slender. Two dorsals, with VI, I 10-11 rays, the spines slender; anal with II 9-10 rays; dorsal and anal fins scaleless. Pectoral symmetrical, rounded or obtusely pointed, with 13 or 14 rays. Caudal subtruncate or rounded, the posterior edge usually slightly emarginate.

## 10. Gymuapogon japonicus, sp.n.

Depth of body 4-5 in the length, length of head 3. Snout as long as eye, the diameter of which is $4-4!2$ in the length of head and nearly equal to the interorbital width. Maxillary extending a little beyond the posterior edge of eyc. Gillrakers as long as gill-fringes, 9 or 10 on the lower part of anterior arch. Dorsal VI, I 10-11, the fourth spine the longest, less than $\frac{1}{3}$ the length of head; longest soft rays about $\frac{1}{2}$ the length of head. Pectoral $\frac{3}{4}$ the length of head ; ventral not extending to anal. Caudal peduncle about twice as long as deep. Olivaceous; caudal often blackish posteriorly.

Numerous specimens, measuring up to 45 mm . in total length.

## 11. Pagrus unicolor, Quoy \& Gaim.

The habitat of this species is thus given by Dr. Fiunther: "New Zealand; Australian Seas. (Chinese Scas?)"

## 12. Sciana albiflora, Richards.

Previously recorded from China.

## 13. Minous monodactylus, Bl. Schn.

Minous Ademsi, Richards., cannot be maintained as a distinct species. I have compared numerous specimens from Japan with examples of M. monodactylus from the Indian Ocean, and am quite unable to see specific differences. I regard Minous echigonius *, Jord. \& Starks, as merely a nominal species; it is based on a single specimen, and the characters which are supposed to differentiate it from N. Adamsi are all subject to considerable variation, as I have convinced myself by examining a large series of examples.

## 14. Pterois Jordani, sp. n.

Depth of body 3 times in the length and equal to the

[^3]length of head. Snout as long as eye, the diameter of which is 3 times in the length of head and twice the interorbital width. Maxillary extending to below anterior $\frac{1}{3}$ of eye. Interorbital space concave, scaly; supraorbital tentacles feeble; supraorbital ridge with 2 or 3 teeth and anteriorly and posteriorly with smaller denticulations; suborbital ridye denticulated, separated from the eye by a space as wide as $\frac{1}{2}$ the diameter of eye; prooperculum with 3 spines. Scales deciduous, about 35 in a longitudinal series. Dorsal XILI 10, the fourth and fifth spines the longest, nearly $\%$ the length of the fish (without caudal). Anal III 6. Pectoral without detached rays, extending to base of caudal; ventral extending a little beyond origin of anal. Caudal peduncle $1 \frac{1}{3}$ as long as deep. Olivaceous; vertical fins pale, the soft dorsal with a few dark spots; pectoral and ventral blackish.

A single specimen, 68 mm . in length to the base of caudal.
Allied to $P$. nigripinnis, Gilchrist, which has a smaller eye and broader interorbital region.

Named after Dr. D. S. Jordan, who has so greatly added to our knowledge of the Fishes of Japan during the last few years.

## 15. Erisphex achrurus, sp. n. (Pl. II. fig. 3.)

Depth of borly $2 \frac{3}{4}-3$ in the length, length of head $31-3{ }_{2}^{1}$. Nuout as long as eye, the diameter of which is $\frac{1}{4}$ the length of head and equal to the interorbital width. Naxillary extending a little beyond anterior margin of eye. Preorbital with 2 spines, the posterior the longer; prexperculum with 4 spines, the uppermost the longest. Body covered with velvety prickles; lateral line with about 12 pores. Dorsal XII 12, the first spine ${\underset{2}{2}}_{1}^{2}$ the length of head, the third and fourth the shortest and about $\frac{1}{3}$ the length of head, from it the rays increase in length to the middle soft rays, which are $\frac{2}{3}$ the length of head. Anal II 10. Pectoral extending to origin of anal or a little beyond. Ventral I 2. Caudal subtruncate. Reddish brown, marbled with darker; dursal, anal, and pectoral with dark markings or nearly uniformly blackish; caudal pale, sharply separated from the dark groundcolour of the body.

Four specimens, measuring up to 70 mm . in total length, from depths of 30-40 fathoms.

Comparison of the largest example with one of E. Pottii, Stdr., of 76 mm ., shows the latter species to differ in having a larger head and larger mouth, as well as in coloration.

## 16. Lepidotrigla Smithii, sp. n. (Pl. II. fig. 4.)

1)epth of body about 4 in the length, length of head 3. Diancter of eye $33^{1}-4$ in the length of had, interorbital width about 4. Snout $\frac{2}{5}$ the length of head or less, with a slightly enarginate or notched and feebly serrated or entire anterior edge, and with a pair of short spinous processes, the distance between the apices of which is equal to or a little greater than the diameter of eye. Maxillary extending to below antcrior margin of eye; depth of suborbital nearly equal to the langh of snout; no distinct traisverse groove behind the orbits. Scales of the lateral line each with a short spine, $58-63$ in number, each of the anterior ones corresponding to two of those below it ; $23-26$ spiny scutes along the bases of the dorsal fins. Dorsal VIII-IX, 15, the second and third spines at equal and $\frac{1}{2}$ the length of head. Anal 14. Pectoral as long as the head, extending to above anterior $\frac{1}{3}$ of anal. Ventral extending a little beyond origin of anal. Caudal truncate. Olivaceous, with a tinge of pink; a blackish spot on the upper part of the spinous dorsal between the fourth and sixth spines; an obscure dark stripe along the soft dorsal ; inner surface of pectoral blackish, with small white spots; other fins uniformly pale.

Five specimens, 70 to 90 mm . in total length.

## 17. Gobius elupoides, Günth.

Pterogotius duimio *, Jord. \& Snyder, should be added to the synonymy of this species, from which it is said to differ in the absence of a band on the caudal. The numerous specimens I have examined certainly belong to one species ; in some there is no trace of a dark vertical bar at the base of the caudal, in others there is a bar or vertically expanded spot, usually rather faintly marked, more rarely as dark as the bars on the body and like them edged with yellow.

## 18. Tridentiger marmoratus, sp. n. (Pl. II. fig. 2.)

Depth of body 5 in the length, length of head $3 \frac{1}{2}$. Snout as long as cye, the diameter of which is 5 in the length of head. Width of osseous interorbital space $\frac{3-5}{4} \frac{5}{6}$ the diameter of eye. Maxillary extending to below posterior edge of eye. $50-52$ scales in a longitudinal series, 16 or 17 between soft dorsal and origin of anal. Dorsal VI, 13, the third and fourth spines the longest, 3 the length of head and a little longer than the longest soft rays. Anal 12. Pectoral f the length

[^4]of head, extending to above the vent. Ventral $\frac{3}{5}-\frac{2}{3}$ of the length of head or of the distance from its base to origin of anal. Caudal rounded. Caudal peduncle $1 \frac{1}{2}$ as long as deep. Brownish, marbled with darker; a dark stripe from eye to upper part of opercle; fins dark greyish ; first ray of each dorsal light, with 3 or 4 blackish spots; anal with a blackish intramarginal stripe; pectoral blackish at the base and with a white cross-bar.

Two specimens, 62 and 74 mm . in total length.
19. Tridentiger genimaculatus, sp. n. (Pl. II. fig. 1.)

Depth of body $4_{4}^{3}$ in the length, length of head 31.2 . Snout shorter than eye, the diameter of which is $4 \frac{2}{5}$ in the length of head. Width of osseous interorbital space $\frac{2}{5}$ the diameter of eye. Maxillary extending nearly to below middle of eye. 55 scales in a longitudinal series, 16 between soft dorsal and origin of anal. Dorsal VI, 12, the third and fourth spines the longest, $\frac{1}{2}$ the length of head and about as long as the longest soft rays. Anal 11. Pectoral nearly as long as the head, extending to above the vent. Ventral ${ }_{4}^{3}$ the length of head, extending nearly ${ }_{4}^{3}$ of the distance from its base to the origin of anal. Caudal subtruncate. Caudal peduncle $1 \frac{2}{3}$ as long as deep. Olivaceous, with obscure darker cross-bars; sides of head with light spots; fins pale greyish; dorsals with alternate light and dark longitudinal stripes in their basal halves; caudal obscurely spotted ; anal with a dark intramarginal stripe; pectoral blackish at the base, and with an indistinct pale cross-bar.

A single specimen, 53 mm . in total lengtl.

## 20. Luciogobius elongatus, sp. n.

Depth of body 10-12 in the length, length of head 7-8. Eyes small, rather widely separated; cheeks swollen; cleft of mouth oblique, extending to below middle of eye. Dorsal and anal fins short and low, the former with about 7 rays, the latter with about 9 . Pectoral about $\frac{2}{5}$ the length of head. Venirals represented by a very small scale-like flap, without distinct rays. Caudal rounded. Olivaceous, with numerous small dark spots.

Several specimens, measuring up to 40 mm . in total length.

## 21. Callionymus ornatipinnis, sp. n. (Pl. III.)

Depth of body 7-8 in the length, length of head (measured to the gill-opening) nearly 4 . Snout lunger than eye, the
diameter of which is equal to or a little less than its distance from the gill-opening. Interorbital space slightly concave, its width $\frac{1}{3}$ the diameter of eye or less. Head covered with smooth skin; maxillary not extending to below the eye; gill-opening small, superior; præopercular spine rather short and stout, 9 the diameter of eye or less, with 3 (rarely 2) recurved spines at the tip and with a small forwardly directed spine at the base. A single lateral line. Dorsal IV, 9. Anal 9. (In one specimen D. IV, 10; A. 10.) Males with the dorsal spines produced into filaments; the second the longest, a little longer than the first and about equal to the distance from tip of snout to gill-opening. Females with none of the dorsal spines produced; the first and second subequal, about $\frac{2}{5}$ of the distance from tip of snout to gillopening. Soft dorsal with the 2 or 3 anterior rays longer than the 4 or 5 succeeding ones, about $\frac{1}{2}$ the distance from tip of snout to gill-opening ; last ray longer, extending to the base of caudal (females) or beyond (males). Caudal fin ${ }_{3}^{7}$ the length of the fish (without caudal) or less. Brownish; upper part of head and body covered with small dark rings enclosing lighter areas ; sometimes 3 or 4 dark cross-bars on the back; usually 3 or 4 blackish spots along the middle of the side. Spinous doraal, in the male, dark greyish, with small light spots with darker centres and a small blackish spot on the margin of the membrane between the third and fourth spines; in the female, pale in front of the third spine, black behind it. Soft dorsal greyish with several series of oval light spots with darker centres, which are smaller and better defined above, and with 1 or 2 series of small blackish spots. Caudal with numerous round or oyal black spots intermixed with light ones. Anal pale. Pectoral pale, obscurely spotted in its upper part. Ventral usually with a blackish bar near its outer margin in the male, but not in the female.

Four males and three females, $98-174 \mathrm{~mm}$. in total length.

## 22. Callionymus lunatus, Schley.

The species figured by Messrs. Jordan and Snyder under this name is certainly not Schlegel's species, but appears to be the Callionymus inframundus of Gill. There are considerable discrepancies between Messrs. Jordan and Snyder's description and their ligure, and it is possible that the former may be in part based on specimens of $C$. lunatus. The male specimen described and figured by Schlegel has the first dorsal spine produced into a long filament, reaching beyond
the end of the soft dorsal when laid back; the last dorsal ray, when laid back, reaches the caudal, which is $\frac{2}{5}$ the length of the fish (without caudal) ; there is a lunate blackish spot on the upper part of the membrane behind the fourth dorsal spine. Three female examples from the Inland Sea of Japan have the first dorsal spine slightly produced, reaching the first or second soft ray when laid back; the last dorsal ray, when laid back, does not reach the caudal, which is $\frac{0}{7}$ the length of the fish; the spinous dorsal is pale, with some darker spots and with a large blackish spot on the upper half of the fin between the third and fourth spines.

## 23. Pseudorhombus ocellifer, sp. n.

Depth of body 2-21 in the length, length of head $3 \frac{2}{5}$. Snout shorter than eye, the diameter of which is $31-3 \frac{2}{3}$ in the length of head. Eyes separated by a ridge. Maxillary extending to below middle of eye or beyond. Gill-rakers longer than gill-fringes, 17 or 18 on the lower part of anterior arch. Scales ctenoid on the ocular side, cycloid on the blind side, $64-72$ in a longitudinal series, 11-13 in a transverse series from dorsal fin to curve of lateral line. Dorsal 68-73. Anal $53-57$. Pectoral of the ocular side $\frac{2}{3}-\frac{3}{4}$, of the blind side nearly $\frac{1}{2}$ the length of head. Caudal with the middle rays the longest, $\frac{1}{t}$ the length of the fish (the caudal not included). Caudal peduncle $\frac{1}{3}-\frac{1}{2}$ as long as deep. Brownish, with darker spots and markings, of which 5 ocelli arranged thus ::- are most prominent; fins with small dark spots.

Total length 125 mm .
Five specimens, including two from the 'Challenger' collection, referred by $\mathrm{Dr}_{1}$. Güuther to $P$. pentophthcimus, an allied species especially distinguished by the smaller eye.

## 24. Pseudorhombus dupliciocellatus, sp. n.

Depth of body $2 \frac{2}{7}$ in the length, length of head 4 . Snout a little shorter than eye, the diameter of which is $4_{4}^{3}$ in the longth of head. Eyes separated by a ridge. Maxillary extending to below middle of eyc. Gill-rakers short and stout, 8 or 9 on the lower part of anterior arch. Scales ctenoid on the ocular side, cycloid on the blind side, 98 in a longitudinal series, 18 in a transverse series between dorsal fin and curve of lateral line. Dorsal 74. Anal 56 . Pectoral of the ocular side ${ }_{3}^{3}$, of the blind side $\frac{2}{5}$ the length of head. Caudal with the middle rays the longest, $\frac{2}{9}$ the length of the fish (the caudal not included). Caudal peduncle $\stackrel{3}{2}$ as long as deep.

Olivaceons, with darker spots and markings, and with 5 conspicuous ocelli or double ocelli, arranged as in the preceding species ; fins with small dark spots.

A single specimen, 350 mm . in total length.

## 25. Cynoglossus purpureomaculatus, sp. n.

Depth of body $4 \frac{1}{4}$ in the length, length of head $5 \frac{3}{4}$. Snout a little more than $\frac{1}{3}$ the length of head. Diameter of eye 8 in the length of head and twice the interocular width. Two nostrils on the left side, one between the anterior parts of the eyes, the other in front of the lower oye. Maxillary extending to below the middle of cye; rostral hook extending a little beyond the mandibulary symphysis. Three lateral lines on the left side. 120 scales in a longitudinal series, 18 between upper and middle lateral lines. Dorsal 128. Anal 104. Brownish, with numerous irregular purplish spots.

A single specimen, 215 mm . in total length.

## 26. Cyneglossus brunneus, sp. n.

Depth of body 4 in the length, length of head $4 \frac{2}{3}$. Snout 23 in the length of head. Diameter of eye 7l in the length of head and 3 times the interocular width. 'Two nostrils on the left side, one between the anterior parts of the eyes, the other in front of the lower eye. Maxillary extending beyond posterior margin of eye; rostral hook extending to below mandibulary symphysis. Two lateral lines on the left side. 74 scales in a longitudinal series, 9 between the two lateral lines. Dorsal 129. Anal 104. Uniformly brownish.

A single specimen, 200 mm . in total length.
III.-Notes on some Oriental Geckos in the Indian Museum, Calcutta, with Descriptions of new Forms. By Nelson Annandale, B.A, Deputy Superintendent of the Indian Museum.

Gymnodactylus Fedtschenkoi, Strauch.
Gymnodactylus cawnus, StoliczLa, Proc. Asiat. Soc. Bengal, xxii. 1853, p. 410.

Gymnodactylus Feiltschenkoi, Strauclı, Mém. Acad. St. Pétersb. xxxv. 1807 , p. 46 ; Boulenger, Famu. Ind., Rept. 1890, pp. 61, (62, and P. Z.S. 1891, p. 630 ; Nikolsky, Herpet. Turan. in Fedtschenko, Reise in Turkestan, p. 1:, pl. iv, figes, 1, 1 a (Rusiau).

There are five specimens from the Punjab Salt Range in the Indian Museum. They are in bad condition, hat agree sufficiently well with Strauch's description of G. Fedtschentioi. The space between the eyes is broader and the head is less depressed than in Nikolsky's figures ; also the chin-shields are larger, the middle pair meeting to form a suture, not a mere point of contact, behind the mental. A male has $3: 2$ pores.

## Gymmodactylus Fec, Blgr.

Gymmoluctylus Fere, Boulenger, Ann. Mus. Genova, (2) xxiii. 1893, pp. 306, 313, 314 , pl. vii. tigs. 1,1 A, 1 в, 1 c.
The only previous record of this species, so far as I am aware, is that of the type from the Karin Hills in Lower Burma. There are three female specimens from Sinkip Island, East Sumatra, in the Indian Museum, presented by the late Professor Wood-Mason. Two of them agree with the trpe in size and coloration, the third is larger and has 8 white bands instead of 9 on the tail. The dorsal tubercles in this adult specimen have a more distinctive character than in the young, the keel being very clearly defined and running along a more or less flattened base.

The dimensions of the large specimen are:-

| Total length | $138$ |
| :---: | :---: |
| Snout to rent | 60 |
| Fore limb | 22 |
| Hind limb | :2, |
| Length of head | $\cdots 1$ |
| Breadth |  |

## Gonatodes marmorutus (Bedd.).

We have a specimen of this species from Tinnevelly, presented by Colonel Beddome. To the same species I refer with a little doubt (but to the genus with certainty) two very young specimens from the Andamans. I am not aware that the genus has been recorded previously from these islands. The specimens were in a bottle containing a large number of examples of Gymnodactylus rubidus of different sizes.

Gonatodes affinis (Stol.).
Giymnodactylus affinis, Boulenger, Cat. Liz. Brit. Mus. vol. i. p. 42.
Gonatodes penanyensis, S. Flower, P. Z. S. 1896, p. $863, \mathrm{pl}$. xliv. tigs. $1,1 \mu, 1 b, 1 c$.

Gomatodes affinis, S. Flower, P. Z. S. 1898, p. 455, and 1899, p. 627; Laidlaw, ibid. 1901, (i.) p. 304 ; Boulenger, Fascic. Malay., Zool. vol. i. p. 148; Annandale, ibid. pp. 148, 149 (note).
This species has not been recorded from the Empire of India or Ceylon, but probably it occurs in Tenasserim. It is by no means rare in the hill-jungles of the northern part of the Malay Peninsula south of the isthmus of Kra; and the greater number of the geckos known from this district have already been recorded from Lower Burma also. Stoliczka's type, from Penang, is in the Indian Museum ; it is in bad condition.

Gonatodes affinis is the only gecko which is known to enter water. Laidlaw has taken it on rocks in a jungle-stream, and I have frequently obscred it slip beneath the surface of water collected in hollows in a tree-trunk and remain submerged for some minutes. When in water the skin of the back has a silvery appearance, owing to the retention of a film of air by the eularged tubercles. Formerly I regarded this as fortuitous; but an examination of the tubercles has made me doubt whether I was right. As Boulenger has noted, they are not merely keeled, but also grooved. Possibly this peculiarity in their structure may assist in the retention of the air-film. The air so retained could not be used in respiration, but it might well protect the organism from a too rapid lowering of temperature, for water in a shady place in the Malayan jungle may be cold.

## Phyllodactylus siamensis, Blgr.

Phylluluctylus siamensis, Boulenger, P. Z. S. 1898, p. 918, pl. iv. fig. 1 ; S. Flower, ibid. 1899, p. 627.

A specimen of this interesting form has lately been presented to the Indian Nuscum by H. W. Biggie, Esq. It is from Pitsanuloke in Northern Siam. An adult male, it has 7 pratanal pores, arranged in a curved line and not interrupted mesially. Its size is considerably greater than that of the type. The following are its dimensions :-

| Snout to vent | $m^{2}$ |
| :---: | :---: |
| Head | 15 |
| Budy | 30 |
| Fore limb | 15 |
| lind limb | 19 |
| Breadh of hea | 10 |

Phylloductylus burmanicus, sp. n.
Allice to P'hyllodactylus siamensis, Blgr. Head longer
than broad, not depressed. Snout short, rounded, shorter than distance between orbit and ear-opening. Body slender; limbs short. Granules on snout and on vertex approximately equal ; only a few enlarged seales on the latter. Dorsal keeled tubercles in 12 rows, smaller than in $P$. siumensis, farther apart. Ear-opening smaller than half the diameter of the eye, subcircular. Nostril between rostral, first labial, and three small scales ; 6 upper and the same number of lower labials. There are 7 preanal pores, arranged as in the preceding species. Colour dark brown above, slightly marbled with paler ; labials marked with pale brown ; throat shaded with dark brown; ventral surface pale brown.

Hab. Távoy.
Both this and the preceding species differ from Boulenger's definition of the genus in the 'Catalogue of Lizards' in that the male is provided with præanal pores.

The species is founded on a single specimen obtained by one of the collectors of the Indian Museum.

## Hemidactylus subtriedroides, sp. n.

Hemidactylus maculatus, D. \& B., Anderson, Res. Yunnan Exped. p. 800.

Closely allied to Hemidactylus triedrus (Daud.), but resembling H. subtriedrus, Jerdon, superficially. Lepidosis as in H. triedrus, except that the dorsal tubercles are smaller, less prominent and farther apart, and that the enlarged scales on the proximal part of the tail are louger and more spine-like. In the male there are 14 to 16 pores, widely separated mesially; 5 or 6 lamellæ under inner, 8 under median digits. Distance from orbit to snout approximately equal to that from ear-opening to orbit. Head and body depressed ; tail depressed, flat above, tapering to a point, broad at the base, flatter and broader at the base than that of $H$. Brookii, Gray. The colour has completely faded (see Auderson, loc. cit.).

Hab. Tsagain, Upper Burma.
The species is founded on two male specimens obtained by one of the Iuman Expeditions under the late Dr. J. Anderson, F.R.S. It agrees sufficiently well with Jerdon's* description of $H$. subtriedrus, which is probably confined to certain districts of S. India; but this description is too vague to be definitive. From Boulenger's $\dagger$ description of this species $H$. subtriedroides differs in the number of digital lamellie and in other important points. The bulk is greater than that of $H$. Brookii, Gray, the dorsal tubereles are larger, and the whole animal is more depressed. The proportions also are different. Anderson identified the specimens as $H$. maculatus, D. \& B.

## Hemidactylus Garnotii, D. \& B.

Ifemiductylus Giarmotii, Boulenger, Fimn. Ind., Rept.p. 94.
Hemidactylus Mortomi, Theobsild, Journ. Lim. Soc. x. p. 32; Boulenger, Fium. Iid., Rept. p. 95.
In the 'Fauna of India' Bonlenger points out that Theobald's deseription of Hemidectylus Mortoni is insufficient to ensure its recogrition. He states his belief that this species is either identical with or closely allied to either II. Bowringii, H. karenorum, or H. Garnotii. After comparing two specimens labelled $H$. Mortoni (one of them presented by Theobald) in the Indian Museum with a considerable number belonging to the thre species referred to, I can see no essential difference between these two specim 'ns and typical ones of $H$. Garnotii, D. \& B., a species which is easily recognized.

## Plychozoon homalocepluthm (Crev.).

Ptychozoon homaloce hatum, Boulenger, Fam. Ind., Rept. p. 10t, fig. 13; Ann. Mus. (ienova, (2) xxiii. 1893, p. 316 ; Fascic. Malay, Zool. vol. i. 1903, pp. 150, 173 ; F. Mïller, Festschr. nat. Ges. Basel, 1892, p. 209, pl. iv.; Gatow, Amphib. Rept. 1501, p. 5l- ; Amnandale, Fascic. Malay., Zool. vol. i. p. 150 (note).

[^5]
## Var. nov. lionotum.

Müller, in pointing out that Ptychozoon Horsfieldii was really a good species, gave as one of the diagnostic characters of $P$. homalocephalum that there are enlarged tubereles among the scales of the back. Boulenger has recorded a specimen, obtained in Pegu by the late Signor Fea, which agrees with the latter species in the more important specific characters, but lacks these enlarged tubercles. Along with several typical specimens of $P$. homaloceplatum from the Andamans and Nicobars we have in the Museum two from Pegu which agree with Fea's specimen from the same district. The occurrence of three cxamples from Pega agreeing thus in lepidosis seems to justify the creation of a new variety for their reception. P. homalocephalum var. lionotum may be defined as agreeing with the typical form of the species in all respects except in having no enlarged tubercles among the scales of the back.

The name of the "flying" gecko enshrines a belief that the loose fold of integument and muscular tissue along the sides in this species has a similar function to the "alar" membrane of Draco, enabling the lizard to take long leaps through the air, and supporting it in that element. That Ptychozoon does take long leaps is very possible. So do Gehyra mutılata and Hemidactylus flaviviridis-forms in which there is nothing of the nature of an aëroplane. A comparison of the "alar" menbrane of Draco with the fold of soft tissue in Ptychozoon shows a very important difference-the latter structure has no skeletal support. Moreover, unlike the membrane of the flying squirrels and phalangers and of Galeopithecus, it is not fastened to the limbs, but has three free edges. It is not even supported by scales below, and although there are muscles at its base-that is to say, on the side on which it is continuous with the body-wall-they do not extend to the free edges. Even if they did, they could hardly keep it taut without direct or indirect support on more than one side from some rigid structure. I have never seen an adult living specimen of Ptychozoon; but a young one, in which the lateral fold was perfectly developed, was kept under observation by Mr. Herbert C. Robinson and myself for a fortnight. We never saw it stretch out the fold, which lay curved round the side so as to be practically invisible. I have not the slightest doubt that the use of the structure is not to support the lizard in the air, but to assist it in concealing itself by causing it to fit better into its surroundings and be less conspicuous than it would be if its body cast a distinct shadow immediately beneath it. The
dorsal surface has a very elose resemblance to lichen-covered bark, and this resemblance is much increased by the lappetlike outgrowths on the tail and head. Hemidactylus platyarus is certainly less conspicuous on a stone wall when its lateral fold (wlich is not so very much less developed than in Plychozom, though this species does not "fly") is spread out on each side of it, as it commonly is. The same is probably the case with Mimetozoon. It is possible also that the folds in these forms have an adhesive function, as outgrowths on the tail have in some geckos; but of this I have no proof. On the whole, the attribution of powers of "flight" to Ptychozoon would seem to be parallel to Cantor's statement that Liolepis Bellii, a sand-loving, burrowing Agamid which very rarely climbs a tree, is in the habit of "leaping from bough to bough." The foundation of this statement was a real anatomical resemblance in certain respects between Liolepis and Draco; but the loose rib-supported membrane in the former has a totally different function from that of the latter, being used (partly, at any rate) as a means of sexual display *. Similarity of structure, even when it is pretty close, does not always argue similarity of function.

## Note.

While on the subject of "flying" quadrupeds, I take the opportunity to restate in a clearer manner a remark recently made about the "flying frog" (Rhacophorus nigropalmatus, Blgr.). In a note added to Mr. Boulenger's "Report on the Batrachians and Reptiles" in 'Fasciculi Malayensis,' Zoology, vol. i. p. 138, I said:-"Beyond the statement of the Chinaman who procured Wallace his specimen, there appears to be no evidence to prove that the 'flying frog' does use its enormous feet to support it in the air, and, so far as we could see, it did not appear likely, from the condition of the web in the living animal, that their purpose was that assigned to them by the discoverer of the species." By the condition of the web I meant its flabbiness. It did not seem possible that it could be rendered sufficiently rigid, and the frog made no attempt to tauten it. Here we have a membrane provided with skeletal supports, but probably only used as an organ of adhesion. Gadow has pointed out how greatly the area of the web was exaggerated in Wallace's figure (Gadow, Amphib. Rept. p. 216, fig. 48; compare Boulenger, Fascic. Malay., Zool. vol. i. pl. vi. fig. 1).

[^6]IV.-Notes from the Gatty Marine Laboratory, St. Andrews. No. XXVI. By Prof. M‘Intosh, M.D., LL.D., F'R.S., \&c.
[Plate IV.]

1. On the Pacific, Atlantic, and Japanese "Palolo."
2. On the British Goniadide, Glyceride, and Ariciida.
3. On the same Groups found in the 'Porcupine' Expeditions of 1869 and 1870.
4. On the same Forms dredged by Dr. Whiteaves, of Canada, in 187. and 1873.
5. On the same Groups procured by Canon Norman in Norway and Finmark.
6. On some Japanese Glycerida.
7. On the Form described as Hemipodus (?) magellanicus in the 'Challenger' Annelida.
8. On the Pacific, Atlantic, and Japanese " Palolo"*.

In connexion with the interesting observations on the "Palolo" of Samoa (Eunice viridis, Gray) by Mr. Mc M. Woodworth in the 'American Naturalist' for December, 1903, a somewhat imperfect digest of which appeared in 'Nature' of March 31st, 1904 $\dagger$, it is well to remember that previous observers had filled in much of the gap. Thus, even in the case of the firstexamples as described by Dr. Gray $\ddagger$, the discoverer, Mr. Stair, stated that the worm came from the coral-reefs. Subsequent observers knew that they dwelt in fissures and crevices of the rocks at and near low water, and that the swarming of the headless portious was connected with reproduction. The first head was described and figured by Dr. J. D. Macdonald $\S$, one of those able naval surgeons, like Huxley and Moss, who have-when on duty on board ship-largely contributed to our knowledge of marine animals. Eunicids are very abundant in cracks and fissures of rocks everywhere, and especially in cural-reefs; but it has yet to be proved that they bore in the latter. Moreover, epitokous annelids have been familiar to zoologists for a long time, and the step to link on the "Palolo" of Samoa therewith was brief, for it was cvidently the posterior region distended

[^7]by the reproductive elements. The main point in Mr. Woodworth's observations was the demonstration of the atokous and cpitokous regions of the body in situ, and as obtained by splitting the edges of the honeycombed coral-rocks. The author attaches much importance to what he calls the thermotropic or heliotropic reaction of the pignent-specks borne on the best-developed central segments of the epitokous region-in comexion with swarming. Further observations are necessary on this head, since similar features are observed in other forms without such pigment-specks.

In the Atlantic "Palolo" (Eunice fucata, Ehlers) from the Dry Tortugas and Porto Rico, a careful account of which was given in 189\% by A. G. Mayer*, a very similar condition precails, the posterior epitokous or sexual region being thrown off by the amelids which live in canals and crevices of the dead and disintegrating coral-rock or corroded "coquina," sometimes along with the commensalistic Polynoë granulata, Lhlers. These sexual posterior regions are broader than in the Pacific "Palolo," and present no pigment-spots, but swim freely away in the same manner-constituting the swarming, which occurs within three days of the moon's last quarter, June 29th to July 28th.

In Britain a condition closely approaching that seen in the foregoing "Palolo" occurs in various forms, e.g. in Nereis Dumerilii, Aud. \& Ed., swarms of which are seen in various bays. Thus they were in rast numbers in Castlebay, Barra, in \ay, and were captured by Dr. Thomas Scott, of the staff of the Fishery Board for Scotland. "Millions" of Nercis longissima were also found by Mr. Hearder swimming at the surface in Plymouth Sound in 1865 . Like other Nereids this is likerrise a favourite bait. An allied condition, that is frec-swimming sexual forms, occurs in the Syllideans, the Cirratulids (Dodecaceria), and many other annelids.
Amongst others Verrill $\dagger$ mentions Nectonereis megalops as a form which "swims actively at the surface both in the evening and in the brightest sunshine in the middle of the day, from July 3rd to August 11th. In this species the palpi appear to be much diminished in the Heteronerecis condition (muless it has some comnexion with Ceratonereis). The males and females of Nereis irritabilis, Webster, when mature, also take to swimming on the surface in the begiming of August. The immature examples live near low-water mark in sand and mud on the Virginian coast.

[^8]But one of the most interesting Nercids in this connexion is the Japanese "Palolo" (Ceratocephale osawai), as recently described and figured in a notewortby paper by Mr. Akira Izuka*, Assistant Professor of Zoulogy in the Imperial Liniversity, Tokyo. The species is much used by the Japanese fishermen as bait, and occurs abmendantly in the littoral region, as well as extends into estuaries, tributaries, canals, and ditches-burrowing in mud to the depth of a foot or mose, like Nereis diversicolor of gur own shores. The species thus approaches the fresh-and brackish-water Nereids from the Pacific coast and Hawaii, as recently described by Mr. II. Parlin Johuson $\dagger$, and extends the list of such forms, which includes Sabellids and others.

The Japanese " Palolo," which has a dark brownish colvur", leaves its burrows in the mud with the flood-tide and creeps about in search of food. It reaches the length of 20)250 mm and is 4 mm . in breadth, and may have as many as 300 segments. In this condition it resembles the ordinary type. Early in September, however, the change to the epitokous form takes place, and the sexes differ in colour, the male being more dusky (brownish) than the female, which is for the most pirt bright red. The body in both sexes considerably increases in breadth. Then the posterior region, comprising about two thirds of the total number of segments, begins to be differentiated--being narrower than the anterior region and of a different colour, dull brommish with a pale streak in the middle. Specimens in this condition are found by digging in the mud about a week before swarming-just as Mr. Woodworth procured his in the coral-blocks. The narrowed posterior region, howerer, is not utilized for the spreading of the eggs or spermatozoa, but degenerates and is cast off, apparently in many cases even before swarming, though a few are found swimming with the shrivelled posterior end attached. Shortly after the change just alluded to, the annelids leare their burrows and become pelagic-swarming near the surface of the water to a depth of several feet, and discharging ova and sperms from the aperture at the end of the anterior region (where the separation of the shrivelled posterior region took place). They are captured at night in great numbers by boats provided with a light, which attracts the annelids, and various nets, and they are much estecm d as bait. The swarming amelids appear to be carried by the tide searrards, though many perish previously by rupture of the body-wall or otherwise.

[^9]The swarming takes place during the months of October and November, usually at four different periods, each lasting a few days ; the periods falling on nights close to the appearance of the new and the full moon and just after flood-tide.

The Japanese "Palolo" therefore differs from both the Pacific and the Atlantic forms not only in regard to the family, but in the nature of the reproductive process, since in both of the latter a specially morlified posterior regionbearing the sexual elements-is separated and swims freely, whereas in the Japmese species the specially modified posterior region degenerates and is shed-the enlarged anterior region swimming actively, discharging its sexual products and then perishing.

Mr. Akira Izuka's paper is illustrated by woodeuts and a coloured plate, the finish of which is in keeping with the excellent illustrations in the ' Economic Fishes of Japan,' by Otaki, Fujita, and Higurashi.

It is probable that the number of forms exhibiting similar features to the "Palolo" will be increased as observations extend.

All the foregoing belong to the temporarily pelagic group, which may be divided into two sections: (1) those which, as larve of reptant or fixed forms, rise to the surface and by-and-by return to the bottom; and (2) those which may come from the shore or the bottom (e.g. epigamous forms) and do not return thereto. Under the latter "Palolo" and the allied forms fall.

## 2. On the British Goniadidæ, Glyceridse, and Ariciidæ.

The British Goniadidæ in Dr. Johnston's 'Catalogne' of the British Muscum included but a single species, though a second was known shortly after its publication. The view of Ehlers that Goniada and Glycinde (Eone) should form one genus has certain recommendations, but it should be remembered that the structure of the dorsal division of the foot, both in soft parts and in bristles, shows a decided divergence, and the same may be said of the teeth. Moreover, Ehlers does not mention that between the body-wall of each of the common forms (Gomiuda maculata and Glycinde Nordmami) there is this difference, viz., that in the latter the dorsal longitudinal muscles have a well-marked fold inferiorly, whilst in the former such is absent. Ehlers, in 1868, grouped them under his Gilycera polygnatha and separated them by the condition of the teeth.

In considering the species of Glycerida mentioned in the

Catalogue of the British Muscum, it would seem that Dr. Johnston's example of Glycera mitis resembled (in 1872) G. dubia in the collection, that is Ghycera siphonostoma, Delle Chiaje ( $G$. tesselluta, Grube), aid had apparently lost its teeth. Two species are thus accounted for. An example of the same species (also labelled G. Rouxii) from Sonth Devon bears out the foregoing diagnosis; yet another specimen labelled G. Rouxii seems to be Glycera lapidum. Glycera nigripes appears to be a varicty of Glycera siphonostoma procured in Scotland by Lieut. Thomas, R.N. Few examples of Glycera lapiclum occur in Dr. Johnston's series, and one or two are in bottles with other species, such as Glycera alba. One example, howerer, labelled by Dr. Johnston "Glycera capitatu," comes from IIoly Island. Another is "Nereis sorex," of Moutagu, from South Devon (Mus. Leach). The additions made to the Catalogue by Dr. Baird consist of the epitokous form of Ghycera capitata ("Glycera setosa") and Glycera alba, O. F. M. It is, however, clear that the former is the epitokous condition of Glycera lapidum, a form closely approaching Glycera capitata and for a long time confounded with it.

The first form, Goniada maculata, CErst., is abundant in the stomachs of haddock in St. Andrews Bay, and ranges from Shetland to the south in fairly deep water. It occurs also in sand at low water. The elongated and tapered snout of cight segments, its pinkish or scarlet colour, greenish eggs, and active habits are conspicuous. The broad region of the proboscis in extrusion is deusely papillose and armed on each side by a row of about ten dark bromn $V$-shaped denticles. Distally are the circle of papilæ and the denticles of the region. The first foot has two somewhat elongated lower lobes (the inferior being the cirrus), with bristles between and above, and superiorly a flattened process representing the upper division. The tenth foot is characteristically trifid, the setigerous region having a single spine and a tuft of bristles superiorly aud inferiorly. At the 50 th foot the dorsal lobe (cirrus) is clongated and tapered, with the dorsal bristles and their spine. The inferior division has a rounded setigerous region with its spiue and two long papille projecting externally. A ventral cirrus occurs inferiorly. The foot remains of similar structure till near the tip of the tail (with its two cirri), the lobes and the bristles increasing in length. The bristles of the ventral lobe considerably excecd the others, their very long terminal pieces projecting far outward.

In glancing at examples of Gioniada from various parts of the world two types of foot are apparent. The first conforms
to the description already given, and which is observed in those from the Outer Haaf and Sierries, Shetland, St. Andrews, Norway, and Canada. The foot is therefore, both anteriorly and posteriorly, the least complex. A tendency, however, to the enlargement of the lobe beneath the dorsal cirrus occurs in females with large ova from Canada.

The second type is represented by examples from Cape Finisterre and Cape Sagres, in which the anterior feet have five processes, viz. a dorsal and a ventral cirrus (the former being near the base of the foot), a long and large posterior lobe, and two smaller anterior. The dorsal lobe is long and narrow and has a slight constriction at its base. In this type the posterior feet have broadly lanceolate dorsal lamellæ, and three long digit-like papillæ inferiorly, above the elongate ventral cirrus.

From the foregoing Glycinde is readily distinguished by its tapering snout of ten segments, its eyes, the two divisions of the body, the structure of the proboscis, and the structure of the feet. The sole British representative, so far as known, is Glycinde Nordmanni, Mahngren, which Dr. Gwyn Jeffreys first procured in various Zctlandic waters. It ranges to several parts of Ireland, to the Atlantic, and elsewheregenerally in somewhat deep water. The proboseis is distinguished from that of the foregoing form by the absence of the lateral V-shaped denticles. The arrangement of the denticles at the termination of the first region of the proboscis scems to differ from Malmgren's figure, which shows a decreasing series of four teeth in lateral view, whereas in some this is not evident. The smaller denticles appear to be from 22 to 24 in number. The first feet are simple and short, bifid and afterwards trifid as they increase in length.

The 10 th foot has three lanceolate lobes. The same number characterizes the 30th foot, but they are more massive and considerably flattened. Between the 30th and 50th feet the appendages attain greater complexity, the latter having a dorsal division of two lobes (or a cirrus and a lobe), a spine, and a few bristles, though the latter are often included in the tissues. This is evidently due to the growth of a dorsal lobe on the upper process of the trifid foot. The lower division consists of an upper long, bluntly conical, setigerous region, with fan-like groups of bristles which are arranged in three divisions, and a ventral cirrus beneath.

A great increase in the lamella of the inferior setigerous lobe occurs at the 70 th foot, so that in outline the parts are broadly lanceolate; the bristles are also longer and more slender. Further changes appear in the l00th foot, for the
lower lobe now far excecds the superior in bulk, the broadly lanceolate outline being due to the approximation of the two flaps. The rentral cirrus is proportionally smaller. In the superior division again the setigerous lobe forms a short and broad cone with the lanceolate cirrus superiorly. With slight modifications this structure continues to the posterior end.

Adranced ora occur in specimens from Ireland and Shetland in July.

Grube and Ehlers have each given classifications of the Glyceridæ, the former basing his main groups on the presence or absence of branchire, the latter using the armature of the proboscis and the nature of the feet to form his chief divisions. Ehlers's first group, the "Glycera tetragnatha," however, includes both of Grube's; the second, the "Glycera polyguatha," comprising Goniudu and Glycinde, being treated separately by Grube. Arwidsson * retains, after Malmgren, the Glyceridæ and Goniadide as separate families, and his paper, illustrated by outline-figures, forms an important contribution to the subject.
The teeth in the Glyceridæ are arranged in pairs, their disposition, horever, being such that they divide the circumference of the estruded proboscis into four nearly equal parts; the larger space, however, often occurring between the two pairs, not between the individuals composing a pair. The pairs of teeth are recognized by the direction of the spurs, which are symmetrically arranged on each side-spur pointing to spur-whether it is simple as in Glycerella or bifid as in the common Glycera lapidum. The single process, bowever, appears always to be longer thau the bifid, and in either case the spur forms a large angle with the tooth which is obliquely inclined to the process.
The first and most abundant British form is Glycera lupidum, De Quatrefages, which stretches along both coasts from north to south, is a common European form, and ranges to the South Atlantic. In its epitokous form (like "Glycer'a setosa") it is found swimmiug at the surface of the sea from Shetland to the Channel Islands, though it is not common in this coudition. This species has the bodysegment three-ringed, the papille of the proboscis are filiform and crenate, and the foot has a single spine in front. At the 33 th foot, however, the dorsal lobe, instead of being folded

[^10]backwards, projects straight outward, and dorsal bristles are present, though the second spine ouly appears about the 45 th foot. The typical foot presents three pointed lobes and a small dorsal cirrus above it, the third or inferior being the conical ventral cirrus, the hind lip being broad and rounded. The ventral bristles are in two fan-like groups, the extreme dorsal and rentral bristles being stronger than the central in the posterior region of the body. This important feature seems to have escaped the patient and persevering labours of Arwidsson, though it is also slightly indicated in G. capitata, Qirst. In the epitokous condition the body is longer, the feet longer and more prominent, and the spines and bristles longer and more attennate. Moreover, simple bristles occur amongst the compound in the ventral series. In contrasting this form with the northern Glycera capitata in its epitokous condition the greater length and slenderness of the bristles is apparent, as well as the less pronounced increase in the thickness of the upper and lower groups of the strong compound bristles.

It was Glycera lapidum w' ich was dredged in the 'Challenger' ${ }^{*}$ off Fayal in the A:ores, not G. capitata, and it was the latter species (as the origimal labelling of the slides as well as the remarks of Ehlers now indicate) which was procured at Kerguclen, but such differed from the ordinary type in the great length of the tips of the compound bristles and in the stoutness of the shafts of the upper and lower series of the same bristles, a feature approaching the condition in G. lapidum. The differences in transverse section between the ordinary form (G. lapidum) and the Kerguclen type, especially in regard to the nerve-cords, were described in the 'Challenger' volume.

De Quatrefages first applied the term Ghycera lapidum to the species described by Dr. G. Johuston as Glycera alba, O. F. M. $\dagger$, and with it he associated Keferstein's Glycera capitata, Cerst. In his description of the species, however, there is little that is definite, for he does not mention whether the segments are two- or three-ringed, though he states that the body is attenuate at both extremities, is devoid of branchiæ, that the head has $8-9$ rings and is very clongate, the feet are short, biramose, have 2 or 3 groups of bristles, and that the superior cirrus is very small, whilst the ventral is large and conical. A perusal of Dr. Johmston's description and an examination of specimens in the British Museum show

[^11]that he refers to the common British species ( $G$. lapidum) hitherto termed Glycera capitata, a species in which the segments are three-ringed. The G. capitata of K eferstein is described by the author as two-ringed, so that (Ehlers and Arwidsson must have satisfied themselves that this is a misapprehension before grouping it with the British form, which is three-ringed.

It is scldom that two forms so closely approach each other as Glycera capitata, Erst., and Gilycera lapidum, De Quatrefages, for the differences in the comparative length of the foot in spirit-preparations are not noteworthy, and the other characters require minute investigation. G. capitata, however, is a purely northern form, characteristic of the waters of Greenland, and not passing farther south than the North Atlantic according to Arwidsson, whilst G. lapidum ranges far southwards. The latter is distinguished from $G$. capitata by having an eleven-ringed cephalic region, pointed foot-lobes, first three feet small and devoid of a dorsal cirrus, ventral cirrus pointed, and dorsal cirrus larger. The papillæ of the proboscis are long and subulate, situated on eighteen longitudinal muscular areas, between which are short ovoid papillæ. The spur of the teeth forms a wide $\mathbf{V}$, whereas in Glycera capitata, Erst., there is but one limb) and a truncated surface (Arwidsson, chiefly). How far future observations may indicate a closer relationship between the two forms is an open question. The differences in structure and distribution are, meanwhile, noteworthy.

Another abundant species is Glycera siphonostoma, Delle Chiaje (G. tessellata, Grube), which has an extensive range from the north of Scotland to the Cape. In this large form the segments are two-ringed and the massive proboscis has lanceolate papillæ each streaked like a leaf. The foot is comparatively short, with an ovoid dorsal cirrus on the body at the base, two long, anterior, broadly lanccolate lobes, about equal in length, and two short, blunt, posterior lobes besides the ventral cirrus, which is of considerable leugth, though it does not extend so far outward as the anterion lobes. The spur of the teeth in the proboscis resembles that of Glycera capitata, Qirst., in having a single process and a flat edge at its base. The body is upwards of a foot in length and nearly half an inch in diameter.

Glycera Ehlersi, Arwidsson?
A species from 80 fathoms in St. Magnus Bay, 1867; 9 miles off Balta, in 80 fathoms, in 1868; and in 53 fathoms on 3rd and 4th August, 1880, in the 'Kuight Errant.'

This differs from any other British form in the structure of the foot and in the greatly elongated snout.

The cephalic cone is much elongated and shows about twenty-two rings with the tentacles at the tip. The papillæ of the proboscis are clongate and conical, whilst here and there are a few with broader tips, so as to be somewhat lanceolate. The teeth present only a single spur of considerable length with a shoulder or flange at the base.

The segments of the body, where most distinct, appear to be three-ringed.

The typical foot has a comparatively large rounded dorsal cirrus with a broad base, two elongated conical lobes anteriorly, and a single median lobe of considerable size-with a rounded edge posteriorly. The ventral cirrus is conical and extends beyond the tip of the latter.

This characteristic form has been in the meantime associated with a species deseribed hy Ehlers as Glycera lapidum *, but which differs from that which has a better title to the name, and therefore Arwidsson has termed it Glycera Ehlersi $\dagger$. It is true it differs from the species described by Ehlers in having apparently three rings to each segment, but in small specimens it is often difficult to apply this character. The structure of the foot of the two forms is the same, though Ehlers has given no figure. Both have a single spur to the tecth-with a flange at its base-and the papille of the proboscis are similar. Ehlers considered that the Glycera capitata of Keferstein $\ddagger$ was his form, but I agree with Arwidsson in referring Keferstein's form to Glycera lapidum.

Amongst those with branchir is the almost cosmopolitan Glycera alba, H. Rathke, which ranges from Britain to Japan and is equally at home in the west of Shetland as on the shores of Devon and Cornwall. The body is of considerable length ( $6-8$ inches) and the segments are two-ringed. The proboscis is short and clavate and the papille small and clavate. The teeth have a long external and a shorter internal spur, both arising from a broad base. The foot is somewhat short anteriorly, longer posteriorly. Branchire are present on all the feet except the first and the last (about twelve at each end) and arise from the dorsal edge of the foot towards the tip. The dorsal cirrus is short, with a constriction at the base. The foot soon shows two spines, two

[^12]flattened lanceolate lobes anteriorly, and behind a shorter conical lobe, whilst a blunt lobe occurs inferiorly. The ventral cirrus is bluntly lanecolate and reaches only to the tip of the truncate lobe just mentioned. The branchia becomes very distinct at the 20th foot, and it diminishes towards the tip of the tail to a small process at the base of the dorsal lobe.

Though it is doubtful whether an accurate diagnosis can be made concerning the Glycera unicornis of Savigny *, yet the descriptions of subsequent authors, more especially those of Malmgren (his G. Goës $i \dagger$ ) and Ehlers $\ddagger$ (who, however, gives it bifid branchie in certain instances), would appear to separate this form. Such branchiæ have not been seen in Britain, and it may yet be necessary to distinguish it from the Glycera Goësi, Nalmgren. In Britain it has hitherto been chiefly found in deep water in Shetland, in the Minch, and off the south-west of Ireland. The head is typical, the body about 5 or 6 inches in length, and the segments tworinged. The proboscis has conical papillæ interspersed with globular ones. The inner spur of each tooth takes the form of that of G. capitata, viz. a ridge which comes near the surface in position and a long bar below. In all the fang has a denticle about the point of origin of the inner spur, and the base of the tooth is set obliquely in the proboscis, so that the distance between the extreme points is considerable. The branchir commence on the 32 nd foot and continue nearly to the posterior end (examples incomplete). The trpical foot has considerable depth, with the comparatively large dorsal cirrus at the base. The branchia is on the anterior surface of the foot and is directed forward and slightly upward. Two long lobes occur at the tip of the foot anteriorly and two shorter flattened conical lobes posteriorly, besides a short ventral cirrus with an oblique and rather blunt tip. The Glycera decipiens of Marenzeller §, from the Bay of Miya in Japan, appears to resemble this species very closely both in regard to the position of the branchix and the structure of the foot; Arwidsson is of the same opinion.

No representative of the family Ariciidæ is entered in Dr. Johnston's 'Catalogue of the Amnelids in the British Muscum,' though under this head he gives several examples of the Spionidæ. The work, however, was only published after his death, and omissions probably occurred, for in an

[^13]illustrated MS. of his which came into my hands in 1872after the death of Dr. Baird-a figure of "Aricio Mülleri" from II. Rathke's 'Beitrige zur launa Norwegens' (1843) is given, as if he had been studying the species.

Several examples of the family have long been known in Britain, the first (Aricia Curieri, Aud. \& Ed.) being perhaps the most common. Its head is a pointed cone without trace of rings or eyes. A transverse line separates it from the peristomial segment ventrally, whilst dorsally a crescent is cut from the latter at the base. The body is from 8 to 10 inches in length, with narrow segments. The peristomial segment is narrow dorsally, but broad ventrally, and the proboseis forms a frilled rosette in extrusion. Posteriorly the body tapers to a blunt point, with the amus at the tip dorsally and with two very long and slender cirri. The first region of the body comprises 21 feet, but these vary considerably amongst themselves, commencing with rudimentary feet anteriorly and ending in modified feet towards the 21st. From the 6 th foot backward the posterior of the three rows of ventral bristles is darker and is composed of spines increasing in strength, so that they form a conspicuous series of brown dots. The foot becomes more free and the posterior row of papille more conspicuous, extending ventrally beyoud the bristles of the $\mathbf{1 7}$ th foot. From the 19 th to the 24 th foot these papilla go to the mid-ventral line. The rows of ventral bristles attain their maximum about the 15 th or 16th foot. The dorsal cirrus increases in size in its progress backward and has an enlargement at the base. The branchice commence at the 5th foot and are of a rich red colour in life. In the succeeding region of the body (at and after the 2:2nd foot) the dorsal division has in front a long tuft of scrrated or articulo-serrate bristles and behind is a large dorsal cirrus with blood-vessels. Below, after an interval, is a smaller cirrus, also with a blood-vessel. The ventral division consists of a setigerous process with a long papilla (ventral cirrus?) and a few very slender bristles of the same type as the dorsal. The peculiarly scrrated bristles disappear posteriorly, long simple tapering bristles taking their places in both divisions of the foot. The majority of the specimens consist only of the anterior region, the posterior having been lef't in the sand or other ground frequented by them as the edge of the dredge severed them.

Aricia norveyica, Sars, again, was found in Shetland by Dr. Gwyn Jeffreys, and extends to Norway and Greenland (Sars and Norman). The head in this species is typical and the anterior regiou has fifteen bristled segments. The
branchix commence on the fifth. The dorsal cirrus is flattened, with a filiform process at its outer edge. The anterior rows of ventral bristles are pale, the last three or four with dark brown hastate spines. The rows of papille behind the foot are more acutely pointed than in the previons species and are from 8 to 12 in number. At the 23 rd foot the dorsal division has 4 or $\overline{0}$ spines and a long tuft of slender bristles with finely tapered serrated tips. The cirrus is narrow and has a tapered extremity. A single spine occurs in the ventral division and a small group of slender bristles, the tips of which are serrated. The blunt setigerous region has a conical lobe to its outer side, whilst at the base externally is a conical ventral cirrus nearly equal in size.

Another of the series is the widely distributed Scoloplos Mïlleri, De St. Joseph, which ranges from the tidal region to 50 or more fathoms, according to the locality. It extends to Northern Europe and the Siberian coast. The acutely pointed head rests on the trumeated cone of the peristomial segment. The body is flattened and widened anteriorly, then rounded ventrally and flattened dorsally in its progress to the tail, which has four papille at the vent and a pair of long slender cirri. The anterior region has eighteen segments, bearing shorter, stouter, serrated bristles. The shorter curved bristles with blunt tips serrated on the convex side are modifications of the longer scrics, apparently due to special influences of habitat, and varying much among themselves. They can scarcely be regarded as a separate and distinctive series. The 15 th foot has a conical dorsal cirrus or lobe, with a tuft of rather long bristles in frout of it, the shafts of which are smooth. The tapering tips are peculiarly spiked, and end in smooth hair-like points. The ventral division has two short conical papille, one of which is below the bristle-tuft and probably represents the ventral cirrus; the other is below the dense, deep row of bristles which are shorter than the dorsal, but of the same type. The branchire commence as small papille on the 17 th bristled foot, attain considerable size at the 20th foot, and almost reach the tip of the tail. Below the foot from the 18th to the 30th bristled segment (fewer in some) a papilla occurs on the side of the body.

To Baron de St. Joseph *, who has done such excellent work amongst the annclids of the French shores, belongs the credit of pointing out the differences between the northern species-the typical Scoloplos armiger of O. F. Mïller-

[^14]and the southern, which he terms Aricia Milleri, H. Rathke. He founds this distinction mainly on the tapering or subulate condition of all the bristles (dorsal and ventral) in the anterior region of Scoloplos armiger, O. F. M., whereas in what he calls Aricia Miilleri such are accompanied by shorter blunt forms, and, morcover, in the first six segments of the posterior region of the body the rentral division has two protuberances below it, with a minute elevation near them, and a conical papilla on the body below. It is not explained, however, that a similar papilla occurs in the typical Scoloplos armiger from Greenland and the northern waters. The two forms very closely resemble each other, the main features which differentiate them being the somewhat longer rows of ventral bristles in the southern, and the better developed fleshy ridge behind them with its flattened conical clevation in the ventral division, aud the two papillre just below it; whilst the rentral row of bristles has a variable number of short and somewhat truncate forms, which must not, however, be regarded as specific. They are simply modified forms of the ordinary tapering serrate kind belonging to the division, and probably are due to the circumstances of habitat, and are perhaps more abundantly present in those from the Chamel lslands than in the more northern examples. In this form a papilla appears in the middle of the fillet behind the ventral bristles of the anterior region about the 5th foot, and is very conspicuous from the l0th to the 13th. At the 17 th foot two papillæ occur, by the addition of one below the median, whilst at the 18th there are three, the bristles being somewhat above (dorsal to) the upper. At the 19 th foot the lateral ridge ends dorsally in three conical processes, with a thick papilla beneath. In very fine examples from Lochmaddy the papilla below the foot commenced on the l5th and continued to the $2: 2 n d$ foot.

The minute differences alluded to in the foregoing paragraphs show the slender grounds on which specific differentiation may be founded. The divergent surroundings may be accountable for some of these, and certainly many examples of Scoloplos Milleri show the effects of abrasion in the anterior bristles of the ventral rows in the first region of the body.

In the typical Scoloplos armiger, O. F. M., from Greenland, the first fifteen anterior fect have somewhat shorter (i.e. from above downwards) ventral rows of bristles. The dorsal cirrus is a well-marked conical process which gradually increases in length posteriorly. The fillet behind the
ventral row of bristles forms a consex flap-highest in the middle-and without any evident differentiation till the 15th foot, when a papilla projects from its median convexity (one or two of the preceding feet showing a slight thickening at the same part). The row of ventral bristles is shorter. Though the bristles are longer, the row is still shorter at the 16 th foot, and a papilla oceurs on each side behind it. The 17 th foot has three papille, whilst the 18th has the cnlarged lateral fillet with an isolated papilla below it, and this for three or more segments.

A form like Scoloplos *, dredged at Station 6, 1100 fathoms, in the 'Valorous' Expedition of 1875, differs from S. armiger and S. Miilleri so distinctly that its features may be mentioned. The snout forms a short cone in front of the large peristomial segment which has the triradiate month inferiorly. The snout in Scoloplos armiger is considerably longer and the peristomial segment smaller. The body is rounded anteriorly, and indeed-so far as the fragmentary specimen goes-throughout, and is thus in contrast with the flattened anterior region of S. armiger and S. Millleri. The dorsal surface of each segment is marked by a narrow ridge round the borders with a depressed area in the middle. Ventrally each segment of the first fifteen has a slight elevation in the middle. The great length and curvature of the dorsal bristles anteriorly is noteworthy. The foot in the anterior region is characterized by the tapering condition of all the bristles, both dorsal and rentral, and in the alssence of the marked differentiation between them. Almost from the 1st foot a minute dursal and ventral papilla are present, and they increase in t!e subsequent feet. These processes in the anterior region form a prominent pair of cirri, which are nearer each other than in the ordinary form. It is difficult to say where the change in the anterior feet occurs, but apparently the first nine are thus differentiated, though it is at the 12 th foot that another flattened and broader process appears above the subulate rentral process or cirrus. The yellowish dorsal bristles have smooth slafts with long, curved, and minutely serrated tips, which vary in appearance according to position, giving a camerated aspect in whole or in part, from the peculiar arrangement of the spinous rows. The dorsal cirrus is in the typical foot a long flat cone. The ventral cirrus is a short conical papilla. The ventral bristles are shorter, with tapering and fincly serrated tips which project only a short distance beyond the

[^15]cirrus. Amongst these are slender, elongate forms which taper to a fine point and do not appear to be serrated. It would seem that the habits of this deep-water form differ from those of $S$. armiger, in which the anterior ventral bristles are much worn.

The processes of the foot become more distinct and gradually pass upward (dorsally), and they are joined by the branchia on the 20th foot. About the 30th foot the seqments increase in antero-posterior diameter, and show a deep furrow laterally and dorsally at the segment-junction, whilst a prominent flap or ridge on the dorsum slopes backward with the various processes, which consist from within outwards of a somewhat short branchia, then of a lanccolate dorsal cirrus with a constriction at the base and the small tuft of iong slender bristles, and, lastly, of a larger and a smaller process, the latter probably representing the cirrus-besides a few slender bristles.

The foot thus differs from the ordinary type (S. armiger) in the less elongate dorsal and ventral cirri.

Canadian examples are characterized by the small size and filiform condition of the dorsal cirras, and also by the somewhat reduced size of the ventral processes. In Scoloplos armiger procured by the 'Valorous' in the same expedition the processes are also more elongate.

A species of Theodisea, viz. T. mammillata, Claparède, has been described by Cunningham and Ramage* from Granton Quarry in the Forth. The details given of this species do not render its exact structure quite clear, and it certainly differs from the Mediterranean fragment procured by the 'Porcupine.'

Naidonereis quadricuspida, Fabr., was procured in considerable abundance between tide-marks at Lochmaddy, North Uist, in 1865. The head forms a round buttonshaped process, the peristomial segment being notched at each side. The body is about 3 inches in length, slightly tapered in front, and considerably diminishing towards the tail, which ends in two rounded dorsal papille and two short ventral cirri. The anterior region has thirteen bristled segments. The branehire commence on the 6th foot, are of comparatively large size, and continue to the 8th or l0th segment from the tip of the tail. At the l0th foot the branchia is flattened and acutely lanceolate, and it is separated by a space from the dorsal division of the foot, which bears a fan-like tuft of tapering bristles with smooth shafts

[^16]and spinose tips. The dorsal cirrus behind has an enlarged base and gently tapered tip. After an interval the slightly conver and long infericr division occurs, with a prominent blunt lobe or papilla rather below its middle posteriorly, and directed inward and backward. A dense scries of the strong and shightly brownish curved (club-shaped) bristles occupies the whole length of the division, with a few tapering, serrated forms amongst them. Most of the short strong forms show distinct serrations towards the curve. The ventral division ends in a notch rentrally. After the change ia the structure of the foot occurs, as at the 23rd, the slightly tapered dorsal cirrus has in front of it a group of long tapering bristles with smooth shafts and serrated tips, which are supported by four spines. A low rounded papilla closely adjoining the foregoing represents the inferior division, with two spines and a few slender serrated bristles. Posteriorly a ventral cirrus appears beneath the division.

> 3. On the Goniadidx, Glyceridx, and Ariciidx of the 'Porcupine' Expedtitions of 1869 and 1870 .
> Goniada pallida, Arwidsson.

In a large but fragmentary example from 81 fathoms, off Cape Finisterre, dredged by the 'Porcupine' in 18\%0, the processes of the feet are proportionally long. A similar form comes from Cape Sagres in the same expedition. In both the ventral bristles are long and strong. The examples are the largest of the series. The head appears to be typical. The body is massive, glistening, and characterized by the clongate fect. It is incomplete posteriorly. The proboscis has two larger teeth, which are somewhat irregular in outline, and more numerous smaller denticles than in G. maculata.

The V -shaped denticles are more numerous than in the common species, viz. 12-13 in number. It is the apex of these which acts on the food. The larger denticles (Pl. IV. fig. 3) are less regular in outline than those of G. muculuta, and the teeth are not in a uniform series. One, indeed, has only a median large and two smaller curved tecth without the lesser processes.

The individuals in the row of smaller denticles varied considerably among themselves, but they did not seem to diverge much from the type seen in the ordinary form. They were, however, much more numerous-smaller being intermingled with the larger. The papille observed did not differ from those of the ordinary form (Pl. IV. fig. 万).

Ann. \& Mag. N. Hist. Ser. 7. Vol. xr.

Arwidsson does not show a postcrior foot（e．g．about 1C0th）， so that there is doubt，but，so far as olserved（PI．IV．fig．1）， it bears a close resemblance to his G．pallida．The compound bristles have the form shown in the same plate（fig．2）．

In the＇Porcupine＇Expedition of 1869，Glyceralapidum， De Quatref．，was dredged off lhundoran in Donegal Bay，on muddy sand，in 20－30 fathoms．

Cilycera siphonostoma，Delle Chiaje，oceurred off Cape Guardia in 1870.

Ghecera alba，H．Rathke，in 1809，was found on muddy sand，in I（＇⿹丁口欠fathe nis，cfí Ireland ；on moddy sand in Donegal Bay，wifundoran，in 20－40 fathoms；and in 30－40 fathems， Dingle lay，amidst stoncs and mad．In 1870 it was dredged in $4 \overline{5}$ fathoms off Cape Sagres，as well as off Cape Guarvia．

Aricia Curieri was dredged in 164 fathoms in greyish sand and gravel in the expedition of 1869.

The second species is Aricia Kupfferi，Ehlers＊，which was dredged in the＇Porcupine＇Expeditions of 1869 and 1870， and which likewise extends to Norway and Greenland．The head in this form is trpical．The anterior region has fifteen bristled sfgments．Wach foot has a dense tuft of spinose bristles finely tapered，with a stout dorsal cirrus posteriorly． An interval selarates it from the ventral division，which has a serics of smilar but shorter bristles，many of which have shafts with rounded tips．The last three feet of the region have dark hrownish spines with long hastate tips．The rows of papilla posteriorly are separated by a space from the bristles．These fapille occur in rows on the ventral surface of bristled segments $13,14,15$ ，and 16 ，and，it may be，on one or two of the succeeding segments．The 23rd foot has the broadly lanccolate branchia intemally on the dorsum， then the elongated dorsal cirrus shaped like a pointed shoe， and a tuft of long serrated bristles，amongst which are some simple forms．There are four spines．In the interval between this and the ventral division is a short and rather broad conical papilla．The ventral division presents a some－ what clavate setigerous region supported by two spines and a prominent lanceolate lobe（cirus）in front of it．The bristles are long and translucent，with smooth shafts and tapering，curved，and closely serrate tips．
＊Tauber seems to be somewhat doubtful if this is other than a var．of A．norevgica，but no papilla exists in the latter，so that this diflers．
4. On the Goniadidæ, Glyceridæ, and Ariciidæ procured by Dr. Whiteaves in the Gulf of St. Lawrence in 1872 and 1873.

## Goniada maculata, Ersted.

In the Canadian examples the V -shaped denticles at the sides of the proboscis ranged from eight upwards. The larger jaws guarded the lateral regions of the organ, their tips pointing dorsally, three bifid denticles occurring ventrally and two $V$-shaped ones dorsally. When the basal region is fully extended the papillæ form a frill at the tip, the teeth of the larger jaws point inwards and backwards, those of the bifid denticles and the tips of the V-shaped forms having a similar direction. Three small separate denticles appeared outside this circle dorsally. The opening of the proboscis in this condition is oblique, pointing uprards and backwards.

## Goniada norvegica, Ersted.

Dredged at A, no. 4, 1872, in 150 fathoms, between Griffin's Cove and Cape Rosier, Gulf of St. Lawrence.

The head is proportionally massive and appears to consist of eight rings in front of the large basal (peristomial) segment. The terminal region has four short cirri, the distal being shorter than the terminal pair. A lateral line or groove on each side dorsally and ventrally cuts off a lateral fillet. The peristomial segment has a slight imprint of the lateral grooves in front dorsally, while ventrally it is split by a wide longitudinal fissure with a flap at each side, forming the lips. No trace of eyes exists in the preparation. The body is about 8 inches in length, though incomplete, and at its widest part is fully 10 mm . across the feet and bristles. It is slightly rounded dorsally, flattened ventrally, with a shallow but broad median groove along the latter. The first segment is connected by a broad median neck with the peristomial, and from this point backward the segments dorsally have a distinct pattern, viz. a broad prominent fillet at each side continuous with a narrower median region, and a narrow fusiform central resion clasped by the former in $\mathrm{f}_{1}, \ldots$ and behind. By-and-u proceeding backward this pattern wome less marked, the lateral fillets being broader, whist the nedian lozenge now eitoncis to the Allet un each side, making, with the former connectun-wir w, two belts between the fillets in each segment. The roiecting fillete alon show furrows (longitudinal). About the
middle of the body considerable flattening occurs and the markings just described fuse and disappear, the segment, with the foot on each side, being only variegated by pigment; and this continues to the posterior end of the fragmentary specimen, in which reproduction of the candal region had commened in the form of a short median papilla with two proportionally large caudal cirri. On the ventral surface the segments are simple in front, then show a tendency to two lateral fillets and two median parts-an anterior broader and a posterior narrower. Posteriorly the segments become simple, as on the dorsal surface, a dimple marking the median region and then disappearing.

The proboscis is a long, tough, and muscular organ, having at the base of its first region two long rows of V-shaped denticles, cighteen in number, with a speck in addition beyond them. At the distal end of this region (in extrusion) are a pair of jaws, near each other, with a dense series of denticles between them, whilst the longer ventral space has a linear series of upwards of twenty in number behind the papillæ. The latter are about seventeen or eighteen in number, blunt and flattened. One of the larger jaws has three prominent teeth, the other three. They lie just within the ring of bluntly conical papillæ.

The first segment bears at each side a small lanceolate lobe on the anterior edge, and on the posterior a foot of three lobes, the rentral being the larger and the dorsal next. No bristles were present in the example. The succeeding feet have four or five lobes, and they increase in size.

Five lobes exist on the 10th foot (Pl. IV. fig. 5), the dorsal being large and lanceolate, with an indentation on the dorsal edge, so that the lobe has the aspect of a foot, the three middle digit-like, and the ventral being a long lanceolate process. The dorsal, ventral, and the posterior lobes reach to the same vertical plane, whilst the two shorter anterior lobes fall considerably within it. Of the two latter (anterior) the upper is the longer.

The 20th foot has the same number of lobes, the large dowal and rentral, two anterior in front of the bristles, and a much larger lobe behind the bristles.

Only compound bristles are present.
About the 35 th foot a small lobe appears in front of the flattened dorsal lobe or cirrus, with a spine and a series of dorsal bristles, thus completing the bifid condition of the foot.

At the 40 th foot is a superior division with a second spine and a group of simple dorsal bristles, the dorsal cirrus or lobe
being somewhat shorter than in front, whilst beneath it is a smaller lanceolate lobe.

The inferior division consists of the three lobes (two anterior and one posterior) and the rentral cirrus. The compound bristles have the same structure.

At the 60th foot a decided increase in the size of all these flattened lobes is observable, especially in the inferior division, and when the l00th foot is reached all may be called foliaceous. The lower dorsal far exceeds the upper in size. The anterior lobes of the inferior division form thin but broadly lanceolate flaps, whilst the posterior is as broad as both and of an ovato-lanccolate outline. The ventral cirrus, again, is shorter than in front, but still broad and thin.

At the change from the more rounded form to the flattencd condition of the body the whole of the processes of the foot become cularged and flattened. Thus the secondary dorsal lobe in front of the superior tuft of bristles has become a double flap with the bristles between. The two anterior and the posterior lobes are also flattened out, whilst the ventral lobe is proportionally less than in front.

Posteriorly the feet diminish in size, but they retain a similar character, the lobes, however, being much less, the largest in proportion being the dorsal (Pl.IV. fig. 6, 90th foot).

The esample is a female laden with large ova.
In considering the relationship of this to the widely distributed Goniada maculata two factors have to be weighed, viz. the effects of environment in causing variation of the sereral parts of the foot and the influence of sexual conditions.

The addition of two lobes to the foot in the anterior region of the body is perhaps the most marked divergence between this and the ordinary type; but as there is variability in the latter on this head, too much reliance need not be placed on it.

There is less difficulty with the posterior feet, which diverge from the ordinary form only by the foliaceous expansion of the identical lobes of the feet, both dorsally and reutrally.

Glycera capitata, Erst., was dredged at Station 54, 1873, off Prince Edward Island, from St. Jaques to Sea-Cow Head.

Glycera siphonostoma, Delle Chiaje, occurred in 187, locality not stated.

## Glycera dibranchiata, Ehlers.

1868. Gilycera dihranchiata, Ehlers, Borstenw. ii. p. 6\%0, Taf. xxir. figs. $1,3-8, \& 19-28$.
From Station no. 7, 1873, viz. between Anticosti and the Gaspé Peninsula, in 100-220 fathoms, come one or two examples of a species which most nearly approaches the Glycera dibranchiata of Ehlers. The form is comparatively small, none apparently exceeding 3 or $t$ inches in length. The head appears to be typical, with numerous closely arranged rings. The proboscis forms a boldly clavate organ in extrusion, and the teeth at the end of the first region can readily cross each other, dorsally and ventrally. The papillæ are elongate, and, by a constriction at the base, somewhat elliptical. At the 10 th foot, two long and somewhat lanceolate lobes occur in front, a short upper one posteriorly, and below it a longer conical lobe. The ventral cirrus is short and conical. The dorsal cirrus is above the base of the foot and of same size. At the 20th foot the chicf change is the increase of the upper posterior lobe, which is a flattened conical plate. The 30th foot presents both a dorsal and a ventral branchia, and these are found as far back as the 90 th ( Pl . IV. fig. 7), and probably behind it in perfect examples. The size of the somewhat ovoid dorsal cirrus remains considerable throughout.

The only example of the Ariciidæ is Scoloplos armiger, O. F. Müller, which was dredged at various stations in 1873, viz., no. 15, in August, in the Baie des Chaleurs, between Capes Despair and Grand; off Pabore, in 70 fathoms; off Cape Hood, Cape Breton, in 45 fathoms, between Bradelle Bank and Miscou Island.

## 5. On the same Groups procured by Canon Norman, D.C.L., F.R.S., in Norway and Finmark.

Of the Goniadidæ, Goniada maculata, Erst., and G. norvegica, CErst., were obtained, and three of the Glyceridæ, viz. : Glycera capitata, Erst., Glycera unicornis, Savigny ( $=$ G. Goësi, Malmgren), and Glycera alba, H. Rathke. Amongst the Ariciidæ are Aricia Cuvieri, Aud. \& Ed., Aricia norvegica, Sars, and a form near Aricia Kupferi, Ehlers, from Norway, and Scoloplos armiger, O. F. M., from Finmark.

## 6. On some Japanese Glyceridæ.

Four species of Glycera have recently been described
from Japanese waters by Mr. J. Percy Moore *, viz. : Glycera Goësi, Malmgren, G. tessellata, Grube, G. alba, Erst., and G. robusta, Ehlers.

It is difficult to diagnose the species mentioned by Schmarda from Chili, as the figures and descriptions of the feet are too indefinite. In his first species, Glycera micrognatha, he describes the branchia on the foot as terminal, but whether the description applies to the terminal papilla of the foot or a branchia is doubtful. The dorsal cirrus is also situated above the foot. In G. macrorhiza the terminal papilla of the foot appears to be his branchia, and the dorsal cirrus is neither shown in the figure nor referred to in the text; yet the form of the foot closely approaches that in the Japanese species. Glycera monodon, Schmarda, again has only a single tooth (?), the same kind of branchia (the terminal papilla), and a short veutral and a dorsal cirrus. The form of the tooth approaches that of the Japanese example. Ilis G.diodon is described as having no branchire, two processes to the teeth, and conical, dorsal, and ventral cirri. The setigerous lobe has a clavate papilla at the tip. It is possible that all the foregoing species and the Hemipoda patagonica of Kinberg may be identical with the Japanese form, as Ehlers thinks, and all appear to belong to the genus Hemipodus, De Quatrefages.

## Hemipodus simplex, Grube, var.

Procured at Koba, Japan, lat. $34^{\circ} 27^{\prime}$ N., long. $156^{\circ} 50^{\prime}$ E., by Capt. St. John, in 1874.

Externally this form differs from Glycera in the somewhat more elongate condition of the body, which appeared to be about 3 or 4 inches in length, and by the wide spaces between the feet. The latter, however, were closer anteriorly and posteriorly than they were in the middle of the body. The head was absent, having been detached after rupture by the proboscis. Posteriorly the body gradually tapered to a tail, which ended in two short cirri.

The first region of the proboscis was longitudinally streaked. The teeth are rather short, with a single slightly curved spur (Pl. IV. fig. 4), which is situated near the basal part or socket of the tooth.

The papille of the proboscis are simple and filiform throughout (Pl. IV. fig. 4), tapering gently from the base to the tip, finely streaked longitudinally and with minute

[^17]granules. They arise from a translucent basement-membrane. They are often curved, but whether this condition has given rise to De Quatrefages's description of falcate is a question. No other form of papilla is present, and hence the surface differs from the figure and description of Ehlers in regard to $H$. simplex, which has clavate or slightly globular forms amongst the filiform. Much depends on the state of the preparation, for a softened one might assume the condition in Ehlers's figure.

The anterior feet are moderately elongate, the dorsal cirrus being above the base of the foot. The setigerous region is bluntly rounded at the tip, which is pierced by the spines, and from the anterior border projects a long digit-like papilla with a constriction at the base. The bristles are placed symmetrically above and below the spine. They all have the same structure, with pale translucent shafts, dilated and split at the end for the insertion of the base of the terminal piece, which is of moderate length with a thick back piece and a thin edge minutely serrated, the whole being finely tapered to a sharp point. None are seen to le bevelled in lateral view-apparently because they differ in this respect from those of such as Nereis. The ventral cirrus is situated at the base of the foot and is somewhat ovoid with a blunt tip-its outline resembling that of the dorsal cirrus.

The posterior feet differ from the anterior in so far as the dorsal cirrus with its constricted base is now situated on the foot, whilst the ventral cirrus has moved outwards to the middle of the foot, is much longer and more pointed. The terminal anterior papilla is also somewhat longer. The bristles do not materially differ: they show a gradation in each bundle, those nearest the spine being more slender than those dorsally and ventrally.

This form has considerably longer feet than that shown by Ehlers, and the ventral cirrus is longer and more pointed posteriorly-in this respect agrecing with De Quatrefages's description of his Hemipodus roseus.

## Glycera alba, H. R.

This form (not to be distinguished from Glycera alba, H. Rathke) comes from a depth of 30 fathoms in the Japan Sea. The papillæ of the proboscis are lanceolate.

A specimen of Gilycera siphonostoma, 6- $\boldsymbol{\gamma}$ inches in length, was found by Captain St. John at low water, 'Tukura, Japan,
in 1874. A comparison with specimens of the species from various localities shows that it is only a variety of this widely distributed form.
7. On the Form described as Hemipodus (?) magellanicus in the Annelids of the 'Challenger' .

This remarkable type of the Glyceride requires, as indicated by the query in the 'Challenger' volume, a now generic name, since it so materially diverges from Hemipodus, De Quatrefages, and also from the types of Kinberg and Schmarda. It is difficult to see why Ehlers $\dagger$ has grouped these different forms under his Hemipodia magellanica, Kinberg; for Kinberg's type, like that of De Quatrefages, whom he followed, had essentially a simple foot (Schmarda's Monosticha) with a single spine and one kind of bristles, whereas the form described in the 'Challenger,' whilst having a simple foot in front, had a bifid one throughout the rest of the body, and two kinds of bristles. The structure of the head of the 'Challenger' species also diverges from that of the types of De Quatrefages and Kinberg. The term Breviglycera magellanica was therefore suggested as more appropriate. Now, howerer, Arwidsson's paper $\ddagger$ has priority, and his generic name of Glycerella may be accepted for this peculiar type, all the features of which were duly pointed out in the 'Challenger' volume.

[^18]
## V.-Rhynchotal Notes.-XXIX. By W. L. Distant.

Subfam. Cicadinge (continued from vol, xiv. p. 430).

## Division Dundubiaria.

This division is composed almost entirely of Oriental, Malayan, and Australasian species, save a few derived from the extreme east of the Palæarctic Region, which, as well known, possesses a strong Oriental affiuity.

The lateral margins of the pronotum are distinctly angulated or toothed ; the tegmina and wings hyaline, sometimes spotted, but never opaque; the opercula vary much in length and shape, and in some genera reach the maximum of development.

This division is a very homogeneous one, but at the same time one of the most difficult to readily analyze. It is hoped that the following proposed generic revision will considerably assist specific determination.

## Synopsis of Genera.

I. Second and third ventral seaments in ol $^{7}$ with distinct lateral tubercles; opercula short.
A. Head (including eyes) considerably narrower than
base of mesonotum

Leptopsaltria.
B. Head (including eyes) as wide as base of mesonotum.
a. Head as long as space between eyes.
b. Tympanal coverings in of broader at base than long.
c. Abdomen moderately conical, gradually attenuated posteriorly, in © considerably longer than space between apex of head and base of cruciform eleration

Purana.
aa. Head as long or a little longer than space between eyes.
$b$ b. Tympanal coverings in of as long as breadth at base, or sometimes broader than long. cc. Abdomen broad, about as broad at apex as at base ; in of not longer than space between apex of head and base of cruciform elevation

Maua.
II. Second ventral segment in of alone provided with lateral tubercles ; opercula short.

Tama.
III. Ventral segments without tubercles; opercula short or sometimes very long, and very variable in shape.
C. Head with the front large and convex, about twice as broad at its base as the anterior margins of the lobes of vertex; rostrum scarcely reaching the posterior coxe

[^19]D. Head with the front not twice as broad at base as anterior margins of the lobes of vertex; lostrum reaching, sometimes passing, the posterior coxæ; opercula long, at least reaching centre, and sometimes apex, of abdomen.
d. Abdomen short, about as long as space between apex of head and base of cruciform elevation.
$\boldsymbol{c}$. Head as long as breadth between eyes.
$f$. Lateral margins of head obliquely continuous to firont or very slightly sinuate. $g$. Head (including eyes) as wide as base of mesonotum.
$h$. Opercula in $\delta$ broad, either just or longly passing middle of abdomen, well separated, and not overlapping, more or less concavely sinuate on each side at basal area, their apices rounded or obliquely truncate.
$\boldsymbol{i}$. Greatest breadth of tegmina about a third of length

Cosmopsaltria.
ff. Anterior margins of vertex of head almost at right angles to front.
ii. Greatest breadth of tegmina more
than one third of length
Fatima.
$g g$. Head (including eyes) only about two thirds the breadth of base of mesonotum

Sawda.
ee. Head much shorter than breadth between eyes.
$h h$. Opercula in ot about twice as broad at apex than at base, their inner margins concave, widening to basal area, outer margins sinuate near centre, their apices broad and overlapping . .
$h h h$. Opercula in $\delta$ broad, their inner margins contiguous, nearly equally broad throughout, their apices broad, the outer margins very obsoletely sinuate.
dd. Abdomen considerably longer than space between apex of head and base of cruciform elevation.
i. Head (including eyes) about as wide or a little wider than base of mesonotum.
$j$. Head about as long as breadth between eyes. $k$. Pronotum measured centrally almost as long as mesonotum excluding cruciform elevation, its lateral margins always distinctly, strongly, and generally acutely toothed.
l. Opercula elongate, concavely sinuate on each side near base, their apices rounded or obtusely acute, nccupying lateral abdominal areas, and always well separated at their inner margins.
ij. Head distinctly shorter than breadth between eyes.
$k k$. Pronotum measured centrally distinctly
shorter than mesonotum, its lateral margins moderately dentate.
ll. Opercula elongate, broad, nearly meet-
ing at their inner margins, sinuate at their basal areas.
m. Anal abdominal segment in $\sigma^{0}$ apically acutely dentate * or with a
broad obtuse process $\dagger$ on each side.
lll. Opercula obliquely divergent, sometimes very short.
$m m$. Anal abdominal segment in ot apically unarmed

Diceropyga.

Meimuna.
llll. Opercula short and transverse.
n. Head (including eyes) about as wide as base of mesonotum, its length about or nearlyequal to space between eyes.
o. Abdomen in $\sigma$ longer than space between apex of head and base of cruciform elevation.
p. Tympanal coverings of normal shape and size.

Pomponia.
Dokuma.
oo. Abdomen in $\delta$ short, about as long as space between apex of head and base of cruciform elevation. ppp. Tympanal coverings of normal shape and size

Aola.
pppp. Tympanal coverings very globose and projecting beyond the lateral margins of the abdomen.

Oncotympana.
2n. Head (including eyes) considerably wider than base of mesonotum ; abdomen long; length of head equal to space between eyes

Champatia.

## Genus Leptopsaltria.

Leptopsaltria, Stål, Hem. Afr. iv. p. 5 (1866) ; Berl. ent. Zeit. x. p. 170 (1866).

Type, L. tuberosa, Sign. (Cicada).
Purana, gen. nov.
Head (including eyes) as wide as base of mesonotum and as long as space between cyes; face prominent and convex, its base ahost at right angles to the anterior lateral angles of vertex; pronotum narrowed anteriorly, its lateral margins angulated or toothed; mesonotum much longer than pronotum ; abdomen moderately conical above, gradually attenuated posteriorly, in male considerably longer than the space

> * As in trpe, D. obtecta, Fabr.
> † As in I. chlorogaster, Boisd.
between the apex of head and base of cruciform elevation, tubercles on the second and third ventral segments large aml prominent; opercula small; tympanal coverings in male broader at base than long; rostrum reaching or a little passing posterior coxæ ; tegmina and wings hyaline.

Type, P. tigrina, Walk. (Dundubia).

## Maud, gen. nov.

Head (including eyes) as wide as base of mesonotum and as long or a little longer than space between eyes ; face prominent and elongately convex, not in a line with vertex ; pronotum narrowed anteriorly, its lateral margins angulated or toothed; mesonotum much longer than pronotum ; abdomen broad, its apex about or almost as broad as base, in male not or scarcely longer than space between apex of head and base of cruciform elevation, tubercles on the second and third ventral segments very large and prominent, opercula small; tympanal coverings in male sometimes as long as, sometimes shorter than, breadth at base; rostrum reaching, generally considerably passing, the posterior cosx ; tegmina and wings hyaline.

Type, M. quadrituberculata, Sign. (Cicada).

## Maua affinis, sp. n.

Closely allied to M. quadrituberculata, Sign., from which it differs by having the outer margins of the opercula almost straight and not convexly sinuate, and by the tegmina, which have the transverse veins at the bases of the second, third, and fourth apical areas infuscated, and also having a small fuscous spot at the apex of each longitudinal vein to the apical areas.

Long., excl. tegm., すै $35-39 \mathrm{~mm}$.; exp. tegm. 101123 mm .

Hab. Borneo (Paris and Stockh. Muss.).

## Tanna, gen. nov.

Closely allied to Leptopsaltria, from which it differs by only having a lateral tubercle on the second and not on the third ventral segment, in other respects resembling the genus Pomponia.

Head (including eyes) narrower than base of mesonotum and about as long as space between eyes; lateral margins of pronotum angularly sinuate, but not prominently toothed;
abdomen much longer than space between apex of head and base of cruciform elevation; tympana covered; opercula small, not or scarcely extending beyond base of abdomen; rostrum reaching the posterior coxæ; tegmiua and wings hyaline.
'T'ype, T. japonensis, Dist. (Pumponia).

## Genus Dundubia.

Dundubia, Amy. \& Serv. Hist. des Hém. p. 470 (1848).
Type, D. mannifera, Linn. (Cicada).

## Genus Cosmopsaltria.

Cosmopsaltria, Stål, Hem. Afr. iv. p. 5 (1866) ; Berl. ent. Zeit. x. p. 170 (1866).

Type, C. doryca, Boisd. (Cicada).

## Fatima, gen. nov.

Head (including eyes) about equal in breadth to base of mesonotum, as long as breadth between eyes, its lateral margins very irregular, the anterior lateral margins of the vertex being almost at right angles to the face; pronotuon little more than halt the length of mesonotum ; abdomen above as long as space between apex of head and base of cruciform elevation; anal abdominal segment in male apically acutely dentate on each side; tympana covered, the tympanal coverings in male projecting a little beyond the lateral abdominal margins ; rostrum passing the postcrior coxæ; opercula in male broad, just or longly passing the middle of the abdomen, either concavely sinuate on each side or slightly and obsoletely sinuate, their apices rounded or obliquely truncate; tegmina and wings subhyaline, the first broad, their greatest breadth more than one third of their length.

Type, F. capitata, Dist. (Cosmopsaltria).

## Sawda, gen. nov.

Itcad (including eyes) about two thirds the breadth of base of mesonotum, and very alighty longer than breadth between eyes, its lateral marcins discontinuous, the anterior margins of vertex being almost at right angles to front; mesonotum only slightly longer than pronotum ; abdomes: short, about as long as space between apex of head and base of cruciform elevation; tympana envered, the flaps a litto
broader than long; rostrum just passing the posterior coxx ; opercula long, their apices broad; tegmina and wings hyaline, their greatest wilth more than one third of their length; anterior femora tuberculonsly spined beneath; anal abdominal segment in male apically acutely dentate on each side.

Type, S. mimica, Dist. (Cosmopsaltria).

## Sawda Gestræi, sp. n.

Head, pronotum, and scutellum olivaceous; area of the ocelli, two central fascie to pronotum (between which the colour is ochraceous), a central lanceolate spot to mesonotum, on each side of which is a posteriorly angulated spot (margined with ochraceous), and a spot in front of each anterior angle of the cruciform elevation, black; there is also a sublateral fuscous streak on each side of the mesonotum ; abdomen purplish brown; body beneath, rostrum, and legs very pale olivaceous; undersides of femora and the tarsi black; tegmina and wings hyaline, the venation pale fuscous; tegmina with the transverse veins at the bases of the apical areas broadly infuscated and a fuscous spot at the apex of each longitudinal vein to the apical areas; the venation at apex of radial area ochraceous; opercula broad, their margins narrowly black and greyishly tomentose, their apices reaching the base of fourth abdominal segment, their outer margins sinuate, but only slightly concave.

Long., excl. tegm., ठ 45 mm. ; exp. tegm. 140 mm .
Hab. New Guinea: Haveri (Loria, Genoa Mus.).
Ayesha, gen. nov.
Head (including eyes) as wide or a little wider than base of mesonotum, much shorter than breadth between eyes, lateral margins obliquely continuous to face or very slightly sinuate, eyes large and oblique; pronotum shorter than mesonotum, its lateral margins angulated anteriorly ; mesonotum moderately convexly tumid; abdomen short, not longer than space between apex of head and base of cruciform elevation; tympanal coverings about as long as broad; rostrum reaching the intermediate coxa; opercula in male. long, about twice as broad at apex as at busc, inmer margin concave, widening to basal area, outer margins sinuate near centre, their apices broad and overlappisig; tegmina and wings hyaline, greatest width of tegmina abont one third their length.
'Type, A. spathulata, Stàl (Cosmopsaltria).

## Haphisa, gen. nov.

Head (including eyes) about as broad as mesonotum, considerably shorter than breadth between eyes, lateral margins obliquely sinuate from eyes to apex; pronotum distinctly shorter than mesonotum, subacutely toothed before middle of lateral margins ; abdomen short, not longer than space between head and base of cruciform elevation; tympana covered, tympanal flaps about as long as broad; rostrum reaching or passing the posterior coxæ; opercula in male broad, their inner margins contiguous, nearly equally broal throughout, their apices convex, their outer margins very obsoletely sinuate ; tegmina and wings hyaline.

Type, H. nicomache, Walk. (Dundubia).

## Haphsa crassa, sp. n.

Body stout, broad, piceous; head with spots at aper of front and the lateral margins of vertex and two spots at base pale ochraccous; pronotum with a central longitudinal fascia, on each side of which are curved discal fascia, anterior narrow margin (broken centrally), and the lateral and posterior margins ochraceous (the posterior margin contains a black spot on each side) ; mesonotum with two long branching discal fascir, commencing at the anterior angles of the cruciform elevation, two short central anterior lines, and the lateral margins ochraceous; cruciform elevation ochraceous, centrally black, and with a black spot on each of the anterior prolongations; abdomen above black, more or less ochraceously tomentose; head beneath, sternum, and opercula very pale testaceous and shortly pilose; abdomen beneath piceous, more or less ochraceously pilose, with a central pale, macular, ochraceous fascia; legs black, the tibiæ (excluding bases and apices) castaneous; coxre, trochanters, and femora streaked and spotted with pale ochraceous; face black, a basal spot and the transverse striations ochraceous; tegmina and wings hyaline, the venation fuscous, the first with the transverse veins at the bases of the second, third, fifth, and seventh apical areas infuscated (sometimes only the second and third infuscated) ; in one specimen there are minute fuscous spots at the apices of the longitudinal veins to apical areas, but in others these are obsolete. Abdomen short and broad, in male about as long as space between apex of head and base of cruciform clevation; length of head considerably shorter than space between eyes; opercula broad, their inner margins contiguous, nearly equally broad throughout, their
apices broadly subtruncate and reaching penultimate abdominal segment; rostrum ochraceous, its apex black, and reaching the posterior coxa.

Long., excl. tegm., ठै $34-38 \mathrm{~mm}$. ; exp. tegm. 97-110 mm. Hab. Yun-nan (Paris and Brit. Muss.).

## Genus Platylomia.

Platylomia, Stål (nom., nec descrip.), Efv. Vet.-Ak. Förh. 1870, P. 708, note.

Head (including eyes) about as wide or a little wider than base of mesonotum, about or almost as long as breadth between eyes ; pronotum centrally about or almost as long as mesonotum (excluding basal cruciform elevation), its lateral margins always distinctly, sometimes strongly, and generally acutely toothed; abdomen considerably longer than space between apex of head and base of cruciform elevation; tympana completely covered; rostrum reaching or passing the posterior coxæ; opercula more or less elongate, concavely sinuate on each side of basal area, their apices rounded or subacute, occupying lateral abdominal areas, always well separated and seldom reaching disk; togmina and wings hyaline, the venation sometimes fuscously spotted.

Type, P. spinosa, Fabr. (Tettigonia).
I use Stall's name for this genus, as the type he proposed (Cic. Alavida, Guér.) is included in it. His description, however, cannot be accepted, as, evidently referring to Guérin's figure only, he states, "ramo venæ ulnaris interioris recto vel leviter curvato," a character given by the artist and not found in the species.

## Platylomia assamensis, sp. n.

Allied to P.umbrata, Dist. (Mrn. Orient. Cicad. tab. v. figs. $11 a, b$ ), and differing principally by the size and shape of the opercula, which just pass the posterior margin of the penultimate abdominal segment, witis their apices suddenly obtusely angulate; the tegmina are shorter, and thus apparently broader, and are without the marginal spots at the apices of the longitudinal veins to the apical areas and the infuscated transverse veins at the bases of tifth and seventh apical areas; the markings of the mesonotum are similar to those of $P$. umbrata, but there is also a distinct black elongate spot on each lateral area.

Long., excl. tegm., ठ 40 mm. ; exp. tegm. 111 mm .
Mub. Assam (Atkinson Coll., Brit. Mus.).
Ann, \& Mag. N. Hist. Ser. 7. Vol. xv.

* Platylomia virescens, sp. n.

Body above shining piceous, more or less greyishly pubescent; anterior margin of pronotum and posterior segmental margins pale castaneous; posterior margin of pronotum greenish or ochraceous; mesonotum with traces of two subolisolete basal obconical spots; abdomen beneath and legs castaneous, anterior and intermediate tibire and tarsi picenus; stemum ochacconsly tomentose ; opercula ochraceous, finely greyishly tomentose; tegmina and wings hyalime, the venation castaneous, basal streaks to both bright, shining green ; tegmina with the transverse veins at the apices of the upper two ulnar areas broadly infuscated, and a small fuscous spot at the apices of the longitudinal veins to apical areas. Body long and slender ; opercula in of terminating in a long slender ontwardly curved prolongation reaching the base of the sixth abdominal segment, moderately concavely simate on each side near base; rostrum just passing the posterior coxr.

Long., excl. tegm., ơ 55 5, ㅇ 46 mm. ; exp. tegm., of if 122-140 mm.

Hab. Borneo: Sarawak (A. Everitt, Brit. Mus.) ; Philippines (Paris \& Brit. Muss.)

In general appearance this species much resembles, nr, to use a somewhat loose term, "mimics," Champakr viridimaculata, Dist.

## Platylomia albomaculata, sp. n.

$0^{\pi}$. Body and legs very dark piceous brown ; abdomen above with a double series of cretaceous spots on each lateral area, the innermost very small, the outer marginal series much larger, a large crefaceous spot on each side of the last abdominal segment ; eyes, apices of intermediate and posterior femora, and the posterior tarsi flavescent, posterior tibise (excluding bases and apices) castaneous; tegmina and wings transparent talc-like, the venation fuscous, extreme bases of both virescent; tegmina with the transverse veins at the bases of the second and third apical areas distinctly infuscated, and with a series of small marginal spots at the apices of the longitudinal veins to apical areas. Opercula somewhat narrow, convexly sinuate on each side near base, the inner and apical margins moderately convexly rounded, their apices reaching the middle of the fourth abdominal segment; rostrum reaching the posterior coxa; face strongly tumid, centrally longitudinally sulcate, and strongly transversely striate.

Long., excl. tegm., ठ 40 mm . ; exp. tegm. 102 mm .
Mub. Philippines (Brit. Mus.).

## Genus Diceropyga.

Diceropyga, Stål, Efv. Vet.-Ak. Förh. 1870, p. 703, note.
Type, D. obtecta, Fabr. (Tettigonia).

## Diceropyga boninensis, sp. n.

Head, pronotum, and mesonotum greenish, or, in faded specimens, ochraceous; head with transverse striations to front, a spot at anterior angles of vertex, area of the ocelli continued obliquely to lateral margins, and a spot at inner margins of eyes black; pronotum with a central black longitudinal fascia, widened anteriorly and posteriorly, and centrally longitudinally pale ochraceous, the incisures, some spots on lateral marginal areas, and the extreme lateral and posterior margins black; mesonotuin with two obconical pale ochraceous spots, the inner margins and lateral areas of which are black, connected with a black spot extending from their apices to cruciform elevation, an irregular black longitudinal fascia on each lateral area, broken anteriorly with pale ochraceous; a small black spot on the anterior and posterior margins of the cruciform elevation; abdomen above black, posterior segmental margins greenish or ochraceous, with macular ochraceous markings which do not extend to the apical third; head beneath, sternum, legs, and opercula pale greenish or ochraceous, the last narrowly margined with black and more or less cretaceously tomentose; abdomen beneath brownish ochraceous; face blackly transversely striate on basal and apical areas, the central sulcation black, with an ochraceous spot at base and apex; tegmina and wings hyaline, venation mostly fuscous brown; tegmina with the costal membrane and area greenish or ochraceous, the transverse veins at the apices of the two upper ulnar areas infuscated. Opercula reaching the apex of the third ventral segment, their apices a little narrowed and rounded, concavely sinuate at outer margins on basal area, convexly oblique at inner margins; anal abdominal segment in male obscurely apically dentate ; rostrum reaching the posterior coxæ.

Long., excl. tegm., of ㅇ $26-33 \mathrm{~mm}$. ; exp. tegm. 8692 mm .

Hab. Bonin Islands and Aluman? (Holst, Brit. Mus.).

## Meimuna, gen. nov.

Heal (including eyes) about as broad as base of mesonotum, shorter than breadth between eyes, lateral margins ouliquely
continuous to face or very slightly sinuate ; pronotum distinctly shorter than mesonotum, its lateral margins distinctly and generally acutely toothed before middle ; abdomen considerably longer than space between apex of head and base of cruciform elevation; tympana covered, tympanal flaps about as long as broad; rostrum reaching the posterior coxa; opercula obliquely divergent, sometimes very short; tegmina and wings hyaline.
'Type, M. tripurasura, Dist. (Dundubia).

## Genus Pomponia.

Pompomia, Stål, Ilem. Afr. iv. p. 6 (1866) ; Berl. ent. Zeit. x. p. 171 (1866).

Type, P.fusca, Oliv. (Cicada).
Pomponia merula, sp. n.
ふ. Body dark castaneous; posterior and lateral margins of pronotum and the sternum more or less dull ochraceous; striations to front and face, and a central spot to first, area of the ocelli and a spot between them and eyes black; black markings on pro- and mesonota generally as in $P$. imperatoria, but posterior margin of pronotum immaculate; a spot between face and eyes, coxæ and femora beneath, tibiæ, more or less, and the opercula black; tegmina and wings pale smoky hyaline, the venation brownish ochraceous; tegmina with the base, costal membrane and area, and spots on transverse veins at apices of first, second, third, and fourth ulnar areas, and near the apex of each longitudinal vein to apical areas, fuscous brown; wings with extreme base and two narrow longitudinal basal streaks fuscous brown.

Allied to $P$. imperatoria, Westw., from which it differs principally by the black, more transverse, and a little shorter opercula, darker colour of the body above and beneath, distinctly narrower and more spotted tegmina, \&c.

Long., excl. tegm., 67-72 mm. ; exp. tegm. 188-194 mm.
Ilab. Borneo, 4 ठे specs. (Sir H. Brooke, Lowe, Hose, \& Everitt, Brit. Mus.). North Borneo: Sandakan (Pryer, Coll. Dist.).

## Pomponia intermedia, sp. n.

Allied to P. imperatoria, Westw., in colour and markings, but differing by the length of the third apical area to the tegmina, which is shorter than the fourth, while those areas are about equal in length in Westwood's species; the greatest
width of the tegmina is scarcely more than a third of their length; opercula ochraceous, narrowly margined with black and obliquely black at base, in shape and length resembling those of $D$. imperatorin. Allied to $P$. merula by the relative breadth and length of tegmina, and by having the third apical area to the same shorter than the fourth, but differing. by the shape and length of the opercula.

Long., excl. tegm., of 64 mm .; exp. tegm. 176 mm .
Hab. Tenasserim: Thaungyang Valley (Col. Bingham, Brit. Mus.).

The structural differences of the three species are expressed in the following synopsis:-

| A. Opercula about as long as broad. <br> a. Greatest width of tegmina much more than a third of their length. |  |
| :---: | :---: |
| b. Third apical area to tegmina about as long as tourth | P. imperator |
| . Grentest width of tegmina about or little more than a third of their length. |  |
| $b b$. Third apical area to tegmina shorter than fourth. | nedia. |
| ercula broader than long | P. merula. |

## Dokuma, gen. nov.

Head (including eyes) as wide as base of mesonotum, its length about equal to breadth between eyes; pronotum considerably shorter than mesonotum, its lateral margin distinctly angularly toothed; mesonotum with a transverse tumidity at and extending beyond the cruciform elevation ; abdomen in male considerably longer than space between apex of head and base of cruciform elevation ; tympana very large, a little convex, nearly meeting inwardly, and between them the prolonged metanotum appears as a longitudinal subconical process; opercula small, between their inner margins a short subglobose metasternal process; rostrum reaching the posterior coxæ; tegmina and wings hyaline; tegmina with eight apical areas, the basal cell longer than broad.

Type, D. nigristigma, Walk. (Dundubia).

## Aola, gen. nov.

Ilead (including eyes) about as wide as base of mesonotum, its length about equal to breadth between eyes ; front prominent, its lateral margins more or less continuous with those of vertex; pronotum distinctly shorter than mesonotum, its lateral margins prominently toothed; abdomen short, about as long as space between apex of front and base of cruciform elevation; tympana entircly covered, the flaps broader than
long ; opercula short, just reaching the first abdominal segment, and not covering the lateral margins of the tympanal flaps; rostrum reaching the posterior coxe; tegmina and wings hyaline, the first with eight apical areas and the basal ceil longer than broad.

Type, A. bindusara, Dist. (Pomponia).

## Genus Oncotympana.

Oncotympana, Stâl, Efv. Vet.-Ak. Förh. 1870, p. 710.
Type, O. pallidiventris, Stål.

## Champaka, gen. nov.

Itead (including eyes) considerably broader than base of mesonotnin, its length about equal to breadth between eyes, latcral margins of front and vertex almost obliquely in line; pronotum about as long as head, its lateral margins armed with a distinct medial spine; mesonotum moderately tumid; abdomen considerably longer than space between apex of head and base of cruciform elevation; tympana covered, tympanal coverings broader than long; opercula short, just reaching basal abdominal segment, laterally oblique and thus exposing the marginal areas of the cavities; rostrum reaching the posterior coxa; anterior femora strongly spined beneath; tegmina and wings hyaline, the first considerabiy longer than the body and with its greatest breadth considerably less than a third of its length; apical areas eight ; basal cell longer than broad.

Type, C. vividimaculata, Dist. (Pomponia).

## TI.-Further Descriptions of new Rhinolophi from Africa. By Knud Andersen.

Rhinolophus Darlingi, sp.n.
Diagnosis.-Differs from all other South-African Rhinolophi by the combination of these two characters: cingula of the upper canine and $\mu^{4}$ in immediate contact with each other; forearm $46 \cdot 7-4 \cdot \cdot 7 \mathrm{~mm}$.

Nose-leaves.-Extreme length 14-145 mm. Horseshoe covering almost the whole of the muzzle; no tooth-like projection on either side of the median notch; greatest width $8 \cdot 1-8.5 \mathrm{~mm}$. Sella naked, slightly constricted below the middle, broadly rounded ofl at summit; vertical height 4 mm. ; breadth at base, at constriction, and at summit
$2 \cdot 1,1 \cdot 5$, and $1 \cdot 7 \mathrm{~mm}$. Posterior connecting-process very short, rounded, in side vicw very nearly semicircular, scarcely projecting beyond the summit of the sella (this kept in vertical position). Lancet very long, scarcely constricted, its lateral margins evenly converging towards the tip ; distance from the posterior transverse bridge to the tip of the lancet 4.2 mm .

Ears.-Reaching tip of muzzle, when laid forward : not attenuated below the tip; this latter blunt. Width of ear about equal to its length from notch on outer margin to tip.

Wings.-5th metacarpal equal to (or only a mere trifle longer than) 4 th. Ist phalans of th finger about $\frac{2}{3}$ the length of end phalun. Plagiopatagium inserted on tarsus.

Tail.-Much longer than the tibia, about the same length as the 3rd metacarpal. Hinder margin of interfemoral triangular.

Colour.-General colour of adult individuals (2 skins) rather dark brownish drab above, "drab-grey" beneath. Base of hairs on back of the same colour as the underside. Length of fur on middle of back about 10 mm .-Immature specimens (2 skins) have a more greyish tinge on the back, but the difference from adult examples is rery slight (but may perhaps be more pronounced in still younger individuals).

Skull.-Hinder border of palatal bridge opposite (or very slightly behind) the middle of $m^{3}$.

Dentition.-Cingula of the upper canine and $p^{4}$ so closely approximated as to completely touch each other. Upper $p^{2}$ quite on the external side of the tooth-row; in one skull ( $q$ ad.) with unworn teeth it is as high as the cingula of the adjacent teeth; in two other skulls with slightly worn teeth it is hair-fine, hardly perceptible without a lens (therefore presumably lost in still older individuals). Lower $p_{3}$, when present, external to the tooth-row, not reaching the upper margin of the cingula of $p_{2}$ and $p_{4}$; in a little more advanced age $p_{3}$ is lost.

Type.-Ad. (skin). Mazoe, Mashonaland, 4000 ft ., June 13th, 1895 ; collected by J. ff. Darling, Esq. B. M. no. 95. 8.27.1. Original no. 35. "Taken in mining adit." Five paratypes (three skins, two in alcohol) are in the British Museum.

Distribution.-A joung Rhinolophus from Angola (B. M. no. (64.8.16. $3^{*}$ ) is indistinguishable from the species here

* Iih. athirps, specimen "e," in Dubson's Cat. Chir", Brit. Mus. (1878) p. 12.
described, in external characters as well as in skull and dentition. Its geographical distribution therefore, probably, is from Angola across South Africa, eastwards at least to Mazoe.

Remarks.-The short diagnosis given above will, in every case, prevent confusion of the present species with any other hitherto known South-African Rhinolophus. Rh. Landeri, lobatus, simulutor, and Denti differ, altogether, in having the upper $p^{2}$ placed in the tooth-row, separating the canine and $p^{4}$ by a distinctly perceptible interspace. Rh. Landeri is much smaller (forearm aloout 43 mm .), with much shorter ears, much narrower sella, higher connecting-process, much shorter tail ( $18-21 \mathrm{~mm}$.), and with the 1st phalanx of the 4th finger peculiarly shortened (less than, or equal to, half the length of the 2nd phalanx). Rh. lobatus, which is of about the same size as $R h$. Darlingi, may at once be scparated by having the posterior connecting-process long, pointed, projecting like a small "horn" far beyond the summit of the sella. Rh. simulator is smaller (forearm $43.5-45 \mathrm{~mm}$.) ; the front face of the sella is "rough," owing to the presence of very short hairs (most easily to be observed under a lens). Rh. Denti is much smaller (forearm $41-43 \mathrm{~mm}$.) ; front face of sella as in $R h$. simulator.

The species is named in honour of Mr. J. ffolliott Darling, to whom the British Museum is indebted for so many valuable accessions to its collection of South-African mammals.

## Measurements.

Rhinolophus acrotis brachygnathus, subsp. n.
Diagnosis.-Like Rh. acrotis Andersoni, but upper and lower tooth-rows, as well as mandible, distinctly shorter.

Skull and dentition (two skulls examined).-Although being apparently, on an average, larger than Rh. a. Andersomi, the present form has a smaller skull, smaller teeth, shorter tooth-rows and mandible (conf. measurements).

Colour.-The general colour of the single skin at my disposal ( $\% \mathrm{imm}$.) is much darker than in the type of Jik. a. Andersoni (o imm.) : greyish "drab" on the upperside, tinged with "mouse-grey" on the hinder back; "ecru-drab" on the underside ; base of hairs on the back of the same colour as the underside.

Type. - $\delta$ ad. (in alcohol). Ghizeh, Lower Egypt, Dec. 16th, 1891; collected and presented by Dr. J. Anderson. B. M. no. 92.9.9.7. There is a second specimen ( 8 imm ., skin) in the Museum from the same locality.

Distribution.-Known only from Ghizeh.
Remarks.-The absence, even in immature individuals, of the lower $\rho_{3}$ and upper $p^{2}$ distinguishes this form sufficiently from the only species with which it could possibly be confounded, viz. Rh. euryale and Rh. clivosus.

Up to the present time three forms of Rh. acrotis have been described: Rh. acrotis (typicus) from Keren, Erytrea; Rh. a. Andersoni from the Eastern Egyptian Desert, about $22^{\circ}$ N., $35^{\circ}$ E.; and Rh. a. brachygnathus from the environs of Cairo.

Measurements of Rh. acrotis brachygnathus and Andersoni.

| Front of upper canine to back of $m^{3} \ldots$. | 7 | $7 \cdot 8$ | $7 \cdot 5$ |
| , lower canine to back of $m_{3}$ | 7.6 | 8.5 | $8 \cdot 2$ |

* It may well be noticed that all the (4) specimens, including the

Ditronosis.-Apparently similar in all essential characters to $R /$ fimmiyatus ( $=$ Antinorii), but decidedly smaller. Forearm 495 mm .

Eaternal characters.-To judge from a dried skin, the shape of the nose-leaves and cars is the same as in Rh. fumigatus. The lateral margins of the sella bear the dense cothing of lone hairs characteristic of the fumigatus-group of species; the hairing on the front face of the sella seems to be sparser and shorter than in the typical form. General colour above dark greyish "drab," darkest on the hinder part of the back, brighter drab on the underside of the body ; base of hairs, throughout, dark smoke-grey.

Mensurements.-Under the next form.
Type.-Ad. (skin). Kitui, British East Africa, 3500 ft., Jan. Srd, 1901; collected and presented by Mrs. H. Hinde. B. M. no. 1.5.6.3. Original no. 68. The type is the only sperimen known to me.

Distribution.-Probably the whole of the Ukamba district.
Remarks. - This is evidently a southern offshoot of Rh. fumigutus, cut off from the (Abrssinian) main stem of the species, and developed into a distinct race. From Rh. Deckeni, an inhabitant of nearly the same regions, it is easily distinguished by the longer and differently shaped nose-leares, by having the margins of the sella clothed with long straight hairs, by the much smaller size (forearm in Rh. Deckeni 54.7 mm .), by having the 4th metacarpal only abont 2 mm . longer than the 3rd (in Rh. Deckeni 5 mm . longer), by the comparatively very short 2ud phalanx of the 5 th finger, \&e. I have not seen a skull of this form; it will, $n o$ doubt, be found to have lost both the lower $p_{3}$ and the upper $p^{2}$, agrecing in this respect with $R h$. fumigatus and differing from Rh. Deckeni.

Rhinolopkius Hildebrandti eloquens, subsp. n.
Diaynosis.-A small race of Rh. Hildebrandti. Forearm $57 \cdot 7-605 \mathrm{~mm}$.

Wings.-Rh. Hildebrandti is among the largest species of

[^20]its genus; $R h . H$. eloguens barely surpasses $R h$. ferrumequimum. The reduction in size affects mainly the forearm and metacarpals, far less the phalanges. In the length of the forearm the largest specimens of $R / h . H$. eloquens fall short of the smullest individuals of the typical form ; this character, therefore, evidently affords a most reliable mark of distinction between the two races. As to the metacarpals, maximum measurements of $R /$. H. eloquens approach, very closely, minimum measurements of Rh. H. typicus.

Colour.-Rh. Hildebrandii (4 skins) is dark greyish "dra')" on the upperside, bright drab beneath. Rh. H. cloquens (3 skins) is tinged with "wood-brown" above, next to "broccoli-brown" beneath. Base of the hairs, on the upper and under sides, dark smoke-grer. Immature individuals (1 skin) are slightly duller in colour than adults.

Skull and dentition.-All the measurements markedly smaller than in typical Rh. Hildebrandti. The length of the upper and lower tooth-rows, as being almost quite independent of the individual rariation, is the best character by which to distinguish between the skulls of the two forms (conf. measurements below). In Rh. Hildcbrandti ( 6 skulls) the upper $p^{2}$ is nearly always present and easily perceptible; the lower $p_{3}$ very minute, but generally not complete! y wanting. In Rh. H. cloquens $p^{2}$ is exccedingly small, hair-fine, even under a strong lens; $p_{3}$ (as it appears from examination of four skulls) almost always wanting, even in immature specimens.

Type.-Ad. (sk.), unsexed. Entebbi, Uganda; collected and presented by F. J. Jackson, Esq. B. M. no. 99. 8. 4.4. Three other specimens, from the same locality, are preserved in the llusemm.

Distribution.-Probably the whole of the district surrounding Albert, Albert Edward, and Victoria Nyanza.

Remarks.-The present form is of great interest from a phylogenetic no less than from a zoogeographical point of view. Rh. Hildebrantti and Rh. fumigatus ( $=$ Antinoriz) * form a well-defined group of species, agreeing in the general form of the ears, in the size and shape of the horseshoe, the sella, and the posterior connecting-process, in having the margins and front face of the sella clothed with long hairs, in the general form of the wings, the comparative shortness of the tail, and the more essential characters of the skull

[^21]and dentition. Until now, however, the very large Rh. Hildebrandti and its small counterpart, Rh. fumigatus, have been without any intermediate link, widely separated in size as well as in geographical distribution. R/h. H. eloquens greatly reduces the gap between the two species; in all the points in which Rh. H. eloquens differs from Rh. Hildebrandii typicus, it "pproaches Rh. fumigatus - in size, in colour, in dentition. Rl. Hildelrandti is decidedly the most primitive form: the upper $p^{2}$ is distinctly perceptible, the lower $p_{3}$ only occasionally wanting; in the Uganda race $\mu^{2}$ is markedly reduced in size, $\mu_{3}$ almost always completely lost ; in the northern Rh. fumiyatus $p^{2}$ is but very rarely present, $p_{3}$ riever. Uganda, the typical locality of $R h . H$. eloquens, is, so to speak, "on the way" between the areas of Rh. Hildebrandti (from Mazoe to Mombasa) and $R h$. fumigatus (S. Somali and Abyssinia). It is not improbable that, when the region between Uganda and Abyssinia is better explored, we shall have to regard Rh. Hildebrandti and Rh. fumigatus no longer as distinct "species," but rather as peripheral forms of one species, bound together by races intermediate in characters and in geographical distribution.

The subjoined table of measurements gives the difference in size, from the smallest form of $R h$. fumigatus to the largest form of Rh. Hildebrandti. If I had been arranging the forms from a phylogenetic point of view, the order would have been just the reverse (the names of the races read from right to left).

VII.-New African Mrommals of the Genera Glauconycteris, Lutra, Funisciurus, Arvicanthis, Lophiomys, and Procavia. By Oldfield Thomas.

## Glauconycteris papilio, sp. n.

Allied to $G$. variegatus, Tomes, with which it has hithertn been confounded ; but the acquisition by the British Museum of the co-types of that species in the Tomes collection enables me to clear up the confusion.

Size smaller than in variegatus (forearm 41 instead of 45). General colour of the ends of the hairs above uniform claycolour from head to rump, exactly matching the posterior back of variegatus, but in the latter the head and shoulders are whitish, the clay-colour being only present posteriorly. Individually the hairs are pale slaty basally, then silvery cream-colour, the tips being pale brownish clay-colour. Under surface uniform cream-buff from chin to anus, the corresponding part of $C$. variegatus being white. Wings and interfemoral membrane variegated as in the allied species. Inner basal lobe of ear rounded.

Skull as in G. variegatus, but shorter, while nearly as broad. Inner upper incisors similarly unicuspid; outer minute.

Dimensions of the type (measured in skin) : -
Forearm 41 mm .
Third finger, metacarpus 40 , first phalanx 15 , second phalanx 27; fifth finger, metacarpus 38, first phalanx 9, second phalanx 9 ; lower leg and foot (c. u.) 27.

Skull: greatest length $13 \cdot 2$; median basal length $10 \cdot 2$; breadth of brain-case $8 \cdot 2$; front of canine to back of $m^{3} 5$.

Hab. (of type). Entebbi, Uganda. Other specimens from Gambaga, Gold Coast (Giffard), and Tette, Zambesi (Boyd Alexander).

Type. B.M. no. 99. 8. 4. 14. Collected 10th April, 1895, and presented by F. J. Jackson, Esq.

Mr. 'Tomes's collection contains six specimens of "Scotophilus variegatus," among which two labelled in his handwriting can be identified as those of which he gave the dimensions in his original description*. Dobson's statement that the type of this species was in the Berlin Museum was therefore erroneous.

The beautiful "butterfly-bat" now described has been

$$
\text { * P. Z. S. 1861, p. } 36 .
$$

litherto considered by de Winton $\%$ and myself as G. variegatus, but it may be readily distinguished by the characters above described.

## Lutra capensis Hindei, subsp. n.

Two years ago I described the Abyssinian representative of the large Cape clawless otter (Lutra capensis) as a special subspecies under the name of Lutra c. Meneleki $\dagger$.

The British Museum has now received from Dr. S. L. Hinde the skin and skull of an old male otter of this group from Fort Hall, British East Africa, where it had been found drowned in a native fish-net. The specimen was skimed and prepared by Mrs. Hinde, whose scientific enthusiasm in performing so serious a task is worthy of much admiration. The only other East-African otter that I have seen is the skin mentioned by W. L. Sclater $f$, which was taken in the Victoria Nyanza and sent home by Col. Delmé-Radeliffe; but that having no skull is of little help for purposes of comparison.

In external characters the Fort Hall otter agrees more closely with South-Atrican specimens than with that from Abyssinia, as it has the wool-hairs of the body broadly tipped with brown as in the former animal, while in the latter they are nearly wholly white. Throughout it is a dark form, the throat less white than in most members of the group, and the dark patches at the bases of the whiskers umasually weil marked. Ears entirely brown, without white edging.

The skull is remarkably small as compared with that of either the Alyssinian or Cape forms, and on this account I think it necessary to give a special name to the animal, calling it Lutra capensis Mindei. The difference may be seen on a comparison of the measurements now given with those of the type of L. c. Menelcki.

The forchead is narrow, the postorbital processes little developed, although the individual is an old one with much worn teeth, and the cranial ridges comparatively low. Nasal opening shaped as in Meneteki, but much smaller. The teeth are of the usual character, but the upper molar is not so large in area or so produced postero-internally as it is in Meneleki.

The following are the dimensions of the skull:-
Basal length 118 mm .; zygomatic breadth 94 ; mastoid breadth 50 ; breadth of nasal opening 18; interorbital

[^22]breadth 29.5 ; tip to tip of interorbital processes 31.5 ; interorbital breadth 26.5 ; palate length (exclusive of mellian spine) 62.5 ; breadth of posterior palate 16 ; antero-posterior diameter of $p^{4} 12 \cdot 9$; greatest diameter of $m^{1} 17 \cdot 5$, anteroposterior diameter of its inner lobe $12 \cdot 1$.

The length of the hind foot (s. u.) is 134 mm . ; ear 21.
Hab. Fort Hall, Kenya District, British East Africa.
Type. Old male, B.M. no. 4. 12. 6. 8. Presented by Mrs. S. L. Hinde.

Since the above was written, Mr. F. J. Jackson has presented to the Museum another specimen of this otter, also a male, obtained some years ago on Lake Naivasha. It agrees very closely with Mrs. Hinde's example in colour an I size, the basal length of the skull being 116 mm . The nasal opening, however, is narrower and higher, it; shape being therefore less constant than might have been expected.

Funisciurus pyrrhopus leonis, subsp.n.
Closely allied to the Gold-Coast $F$. p. leucostigma, Temm., but with the following differences:-Middle of crown and top of muzzle dark olivaceous like the back, the rufous or yellowish which surrounds the eyes not extending across the muzzle as it does in leucostigma. Ears larger, conspicuously white behind, the white forming also a prominent postauricular patch behind their posterior bases; in leucostigma, although there is some white behind the ears, it is much less conspicuous and less extended. Light lateral band narrower. Flanks a richer rufous than in leucostigma; the outer sides of the hips especially rich rufous; in leucostigma the sides of the hips are only a dull suffused fulvous. Middle of underside of tail dull and inconspicuous rufous, instead of bright and prominent fulvous or rufous.

Dimensions of the type (measured in the flesh) :-
Head and body 200 mm .; tail 150 ; hind foot (s. u.) 44 ; car 12.5.

Skull : greatest length 49; length of upper tooth-series $9 \cdot 5$.
Hab. Bo, Sierra Leone. Altitude 120 m .
Type. Female. B.M. no. 4. 11. 1. 5. Collected 20th January, 1904, by Mr. Robin Kemp. 'Two specimens.

It is to be noticed that while the flanks and sides of hips are more rufous than in leucostigma, the muzzle and the moderside of the tail are less so. The white on and behind the ears is also noticeably more conspicuous.

## Arvicanthis setosus, sp. n.

A pale-coloured species without dorsal stripes.

Size medium. Fur long, the ordinary hairs of the back about $11-12 \mathrm{~mm}$. in length, profusely mixed with much longer bristly hairs, averaring $20-22 \mathrm{~mm}$. in length on the rump. General colour pale yellowish grey, the hairs each with a broad buffy yellow subterminal ring, the whole very heavily lined with the black tips to the ordinary hairs. Tips of long sete of rump buffy yellowish. Under surface greyish white, the bases of the hairs slaty, their tips white; no sharp line of demarcation on sides. Sides of muzzle and orbital rings yellow. Ears yellowish brown. Outer side of limbs like body; inner side thimly haired, but not naked, whitish; upper surface of hands and feet dull buffy white. Tail black above, dull whitish below and on the sides.

Skull of normal size and proportions, the incisors not unusually large. Palatal foramina narrow, little open, reaching just behind the anterior point of $m^{1}$.

Dimensions of the type (measured by the collector) :-
Head and body " 110 " mm . (probably more) ; tail 112 ; hind foot 29 ; ear 17.

Skull : greatest length 32 ; basilar length $26 \cdot 3$; zygomatic breadth 17 ; length of nasals 11 ; interorbital breadth 45 ; breadth of brain-case 14; palate length 145 ; diastema 8 ; palatal foramina $6.1 \times 1.5$; length of upper molar series 6.8 ; breadth of $m^{1} 2 \cdot 1$.

Ilab. Fra-Fra Country, Gold Coast Hinterland. Alt. 150 m.
Type. Male. B.M. no. 99. 6. 15. 13. Collected 7 th February, 1899, and presented by Capt. W. Giffard.

This species is much paler and yellower than A. rufinus, the only other W.-African species without dorsal lineation.

## Lophiomys testudo, sp. n.

As long ago as 1898 Mr. F. J. Jackson made the first discovery of the remarkable genus Lophiomys in East Africa, and presented the specimen which he had captured at the Ravine Station to the National Museum. Being in doubt as to its relationship with the Somali Lophiomys Smithii, Rhoads, Mr. de Winton, when working out Mr. Jackson's collection, made no reference to the Lophiomys, but afterwards incidentally mentioned it in Anderson's'Mammals of Egypt' ".

In 1902 Mr. C. S. Betton presented to the Muscum two further specimens, which had been captured, the one by himself and the other by Mr. S. Couper, in very much the same region.

A comparison of this material with an Abyssinian example
of L. Imhausi, and with Mr. Rhoads's description * of L. Smithii, convinces me that the E.-African form is quite, distinct from the others, and I would propose to call it Lophiomys testudo.

Size smaller than in L. Imhausi, larger than in L. Sinitliii. Long hairs of back about 65 mm . in length, broadly tippel with white on body, limbs, and tail. Uuderfur about 4.)50 mm . long, as compared to 20 in L. Smithii, the length to the base of the black terminal band about 27 mm . Basal third of the underfur dark brown, middle third white, tip black, the contrast between the colours more marked than in L. Imhausi. Suborbital white spot well marked. Dark band dividing the frontal from the auricular white patch scarcely perceptible. Inner aspect of ears broadly margined above with white, but the lower half is dark brown, including the base of the outer margin. Hairs of lateral line olive. Under surface hoary grey, not darker along the median line. Upper surface of hands and feet blackish. Tail with its underfur mixed whitish and black, the tip for a length of about half an inch sharply contrasted white.

Skull larger and, especially, markedly broader than in L. Smithii. Nasals narrower behind than in front. Interorbital more than half the total frontal breadth. Small keystone portion of squamosals separating the frontals from the rugose wing of the molars long antero-posteriorly ( 4.5 mm .), narrow ( 2 mm .) transversely. A marked angular concavity on the outer side of the maxillary zygomatic process just in front of the anterior angle of the malar. Palatal foramina comparatively short, ending just anterior to the front edge of $m^{2}$.

Dimensions of the type (measured in the flesh) :-
Head and body 296 mm . ; tail 176 ; hind foot 44 ; ear 29.
Skull : greatest length $58 \cdot 2$; basilar length $47 \cdot 4$; greatest breadth $37 \cdot 5$; nasals, length $20 \cdot 5$, anterior breadth $8 \cdot 8$, posterior breadth $7 \cdot 5$; interorbital breadth $13 \cdot 5$; greatest frontal breadth $24 \cdot 2$; palate length 2.7 ; diastema $15 \cdot 1$; palatal foramina $9 \cdot 3 \times 4.3$; length of upper molar series $12 \cdot 6$.

Hab. (of type). Ravine Station, British East Africa. Mr. Betton's specimens from El Burgon Station and Mile 513 of the Uganda Railway.

Type. Female. B.M. no. 99. 8. 4. 97. Collected 10th March, 1898, and presented by Mr. F. J. Jackson.

This East-African representative of the genus Lophiomys differs from its nearest ally, L. Smithii, Rhoads, by its longer

$$
\text { * Pr. Ac. Philad. 1896, p. } 524 .
$$

Ann. \&e Mag. N. Hist. Ser. 7. Vol. xv,
underfur, much broader skull ( 37.5 mm . as compared with 31 ), and shorter palatal foramina, which do not penetrate between the molars.

There is a certain amount of difference between the typical skull obtained by Mr. Jackson and that presented by Mr. Betton in the detailed proportions of the parietals and squamosals and in the form of the anteorbital foramina; but without further specimens it is impossible to express any opinion as to the cause or value of these differences.

Since the above was written Mr. S. L. Hinde has presented to the Museum another specimen of this animal obtained by him on the Abudau Range at an altitude of 10,000 feet. It agrees with the type in all important respects.

## Procavia Goslingi, sp. n.

A hypsodont species with an elongate orange-coloured dorsal spot.

Fur rather short, though not harsh; hairs of back about $16-17 \mathrm{~mm}$. in length. General colour above from nape to rump dull sandy yellowish, something between Ridgway's " isabella" and "clay-colour," slightly speckled with black on the posterior back. Basal half of the hairs dark chocolatebrown. Under surface and inner side of limbs dark buffy, the line of demarcation on sides not sharply defined. Head greyish brown ("hair-brown") without yellowish suffusion, conspicuously different from the rest of the upper surface; top of muzzle darker. Ears of medium size, rounded, their outer surface yellowish grey, inconspicuously edged with black anteriorly; inner surface glossy yellowish. Outer side of limbs and upper surface of hands and feet to the hoofs greyish fawn, less suffused with yellow than the back. Dorsal spot narrow, elongate ( $40 \times 7 \mathrm{~mm}$.), its hairs uniformly deep orange from base to tip.
skull as usual in this group, its general proportions as shown by the measurements.

Dimensions of the type (measured in skin) :-
Head and body 450 mm . ; hind foot 67.
Skull (stage iii.): basal length 72 ; greatest breadth 4.5 ; nasals $19 \times 215$; diastema 11 ; breadth of $m^{2} 7.5$; height of $m^{1} 7 \cdot 1$.

Ilab. Nertang, Yerghum Country, Northern Nigeria. Alt. 360 m .

Type. Immature male. Original number 24. Collected 29 th June, 1904, and presented by Capt. G. B. Gosling.

Native names: in Yerghum "Chium"; in Hausa, "Rema." - (t. B. Gosling.

This remarkably coloured dassy is quite unlike any species known to me. Its nearest ally is probably $P$. Kerstingi, Matschie *, from E. Togoland, but that has wholly black backs to its ears, and the hairs of its dorsal spot are dark for their basal halves.

> VIII.-Eocene Shells from Nigeria. By R. Bullen Newton, F.G.S.
[Plate V.]
The names of the shells about to be described in this paper have already been published in list-form by the present writer $\dagger$ in ' The Geographical Journal' for November 1904, accompanied by a digest of the literature bearing upon the palrontology of Nigeria and adjacent territories.

The specimens were collected by Colonel G. S. McD. Elliot, R.E., and Captain Lelean, R.A.M.C., of the AngloFrench Niger-Chad Boundary Commission, atKalfu-Tamaskie and Garadimi, in Northern Nigeria, and subsequently presented to the Geological Department of the British Museum by those officers.

A few general points of interest connected with these shellremains are referred to in the following quotation, from the article in 'The Geographical Journal' :-
"Some of these specimens are preserved as limestone-casts, among them being several Lucina, which I have called L. cf. Menardi and L. cf. pharaonis, and which represent most probably the forms referred to in Lapparent's papers as $L$. cf. gigantea. All three species, however, are typically Eocene, and have mostly been recorded from Egypt or Southem European countries. The specimens of Alectryonia cf. Martinsi, originally described from India by J. de C. Sowerby under the name of Ostrea orlicularis, help to support the theory that this ancient sea had an extensive eastward direction in Eocene times. The peculiar Ostreiform geuus I'ulsella

[^23]may also be referred to as characteristically Eocene, whilst among the Gastropods Volutilithes cithara is important from the distribution point of view, being known from the Eocene areas of England, Europe, Egypt, and India."

Moreover, everything seems to prove that this fauna is of Middle Eocenc or Lutetian age, thus confirming the opinion of Professor A. de Lapparent *, who first made us acquainted with the presence of rocks of that horizon in the Soudan area of Africa, from an examination of fossils obtained by Captain Gaden at the same locality as yielded those collected by the British officers, viz. Tamaskie, which is said to be 400 kilometres west of Zinder. These fossils comprised the following Mollusea and Echinoids, the latter having been determined by M. Victor Gauthier :-

The distribution of Eocene rocks in African territory north of the Equator appears to be very considerable, since fossils have been recorded of that age from the Cameroons by Dr. Paul Oppenheim $\dagger$, which were obtained by Dr. Esch, the same palrontologist having also evidence of the Eocene formation at Dahomey from a shell submitted to him by Dr. Joh. Boehm ; and, again, Prof. G. Vasseur $\ddagger$ has reported the occurrence of Eocene Foraminifera found at a depth of 230 metres in the kingdom of Senegal. In the more northern and eastern parts of Africa these rocks are again largely developed (including Marocco, Algeria, Egypt, Somaliland, \&c.), so that it is quite certain that the Eocene sea must have covered an extensive area of that continent in ancient Tertiary times.

[^24]
## Description of the Specimens.

## Lamellibranchia.

## Ostrea rarilamella?, Deshayes.

Ostrea rarilamella, Deshayes, Desc. Anim. sans Vert. 1861, vol. i. pls. Ixxxi., lxxxii., \& vol. ii. p. 109 ; Archiac, in Tehihatchefl's 'Asie Mineure,' Paléontologie, 1866-1869, pl. x. \& pl. xi. fiy̌. 1, p. 135 ; Zittel, Palæontographica [Libyschen Wüste], 1883, vol. xxx. p. cxi.
The specimen, referred doubtfully to this species, consists of a fragment of an upper valve without, however, its hingearea. It shows great thickness of shell-structure ( $=13$ millimetres), somewhat distant lamellæ of growth, and a portion of an extensive scar-impression. Beyond the scar-margin the surface of the valve is rounded, smooth, slightly undulating, and dipping towards the outer edge. In the absence of more perfect material, a closer determination is scarcely possible, although the general facies of the specimen compares favourably with the figures and descriptions of this species.

Loc. Kalfu-Tamaskie.
Collector. Colonel Elliot.

## Alectryonia cf. Martinsi, Archiac.

Ostria orbicularis, J. de C. Sowerby, Trans. Geol. Soc. London, 1840, ser. 2, vol. v. pt. 2, pl. xxiv. fig. 8, non Linnæus.
Ostrea Martinsí, Archiac, Mém. Soc. Géol. France, 1850, sér. '2. vol. iii. pt. 2, pl. xiii. fig. 25, p. 438.

This form is represented by two fragments of a small, depressed, suborbicular, and ostreiform shell having both its valves plicated, and therefore a true Alectryonia. Its shape and the bifurcation of the strong, prominent, and rounded costre suggest affinities with $A$. Martinsi, from the Eocene beds of Cutch and Biarritz, though probably the valves of that shell are rather more convex.

Loc. Kalfu-Tamaskie.
Collector. Colonel Elliot.

## Vulsella nigeriensis, sp. n. (Pl. V. figs. 4, 5.)

The collection contains a small subcircular form of $\mathrm{V}_{\mathrm{u}} \mathrm{l}$ sella of greater horizontal than vertical measurement. The umbones are nearly central, divergent, and acute, whereas the sides of the valves are furnished with about nine convex radial costr separated by shallow grooves, which proceed
from just below the umbonal area. Where the original shell is preserved, it is seen to be ormamented with very fine concentric striations originating from the summits, having the tendency of rendering the radial costre somewhat indistinct. The specimen likewise possesses a well-sculptured triangular chondrophore (fig. 5), so characteristic of the genus, the outer posterior sides of which form a pseudo-alation extending from the divergent summits.

Both valves of the specimen are in the closed condition.
Vulsella is a characteristic genus of Eocene rocks, the present species mainly differing from other described forms in its rounder and more depressed valves.

Dimensions. Umbono-ventral 27 mm .; antero-posterior 30 ; diameter 11.

Loc. Kalfu-Tamaskie. Collector. Colonel Elliot.

## Spondylus cf. subspinosus, Archiac. (Pl. V. figs. 6, 7.)

Sppontylus subspinnosus, Archiac, Mém. Soc. Géol, France, 1850, sér. 2, vol. iii. pt. 2, pl, siii. fig. 1, p. 437 (Biarritz) ; and in Tchihatchett's
'Asie Mineure', 1866-1869, Paléntologie by Archiac, pl. xi. figs. 2, 3, p. 149; R. B. Newton, Quart. Journ. Geol. Soc. 1904, vol. 1x. pl. xxiv. figs. 24 \& 25, p. 289 (Turkey).
This form of Spondylus, although related to $S$. subspinosus, a species found in the Eocene rocks of Biarritz, Turkey, and Asia Minor, is slightly more convex, and has a greater number of costr, and consequently narrower longitudinal grooves. The sculpture-striations (fig. 7) are, however, very similar, being close together and nearly horizontal. The only example found was the larger or lower valve.

Dimensions. Umbono-ventral 48 mm .; antero-posterior 40 ; diameter 20.

Loc. Kalfu-Tamaskie.
Collector. Colonel Elliot.

## Cardium sp.

This specimen consists of a rough cast showing no sculpture characters, but possessing closed valves with a greater height ( = umbono-ventral measurement) than length ( $=$ anteroposterior measurement), and showing subcentral and rather convex umbones, the hingc-area being somewhat shortened. It is almost impossible from its condition of preservation to suggest any species with which this specimen might be related, although its oblong and subglobose form resembles Cardium gratum of Deshayes, a European Eocene species,
which has recently been recorded by Oppenheim from Egyptian rocks of similar age (' Palæontographica,' 1903, vol. xxx. part 3, p. 15̌3) ).

Dimensions. Umbono-ventral 40 mm ; antero-posterior (approximate) 37 ; diameter 24.

Loc. Kalfu-Tamaskie.
Collector. Colonel Elliot.
The following casts of Lucina probably comprise what Prof. de Lapparent has referred to under the designation of Lucina cf. gigantea :-

Lucina cf. Menardi, Deshayes. (Pl. V. fig. 8.)
Lucina Menardi, Deshayes, Desc. Coq. Foss. Paris, 1825, vol. i. pl. xri. figs. 13 \& 14, p. 94.
Lucina Menardi?, Bellardi, Mem. R. Accad. Sci. Torino, 1854, ser. 2, vol. xт. p. 188.
This form is represented by three limestone-casts with closed valves in very fair condition of preservation. It is of larger size than $L$. pharaonis, and showing coarser radial striations. It differs also from L. gigantea in possessing more ventricose valves.

One of the specimens (fig. 8) from Kalfu-Tamaskie exhibits the long, narrow, anterior adductor scar lying slightly ab, ve the pallial line. The size of the same specimen agrees with the published figures of Deshayes, which are said to be of natural size, a statement which, however, does not agree with the text, where greater dimensions are given.

Dimensions (the Garadimi specimen). Umbono-ventral 56 mm .; antero-posterior 58 ; diameter 26.

It is interesting to note in connexion with this determination that Bellardi doubtfully referred an Egyptian fossil to this species.

Locs. Kalfu-Tamaskie and Garadimi.
Collectors. Colonel Elliot and Captain Lelean.

## Lucina cf. pharaonis, Bellardi. (Pl. V. fig. 9.)

Lucina pharaonis, Bellardi, Mem. R. Accad. Sci. Torino, 1854, ser. 2, vol. xv. p. 190, pl. ii. fig. 12; Oppenheim, Palæontographica, 1903, vol. xxx. pt. 3, pl. xiii. figs. 1 \& ${ }^{2}$, and pl. xv. fig. 6, p. 124.
Represented by natural casts with closed valves of various sizes, agreeing in its nearly circular shape and diameter with the same form from Egypt, as figured quite recently by Dr. Oppenheim and previously by Bellardi and others. The Nigerian casts exhibit numerous fine longitudinal striations
radiating from the umbonal area which are so characteristic of the internal surface-structure of Luciniform shells.

Dimensions. Umbono-ventral, largest 52 mm ., medium 46 ; antero-posterior, largest 59, medium 47 ; diameter, largest 23 , medium 20.

Locs. Kalfu-Tamaskie and Garadimi (fig. 9).
Collectors. Colonel Elliot and Captain Lelean.

## Lucina sp. indet.

Specimen consisting of a natural cast of a Luciniform shell with closed valves possessing nearly central umbones and exhibiting rather wide concentric sulcations. There are also obscure indications of an angulated posterior area. It is of oval shape, somewhat resembling Fimbria lamellosa; but as that species has a more complicated sculpture, and is, moreover, without an angulated area, it need not be confused with the present specimen.

Dimensions. Umbono-ventral 40 mm . ; antero-posterior 58 ; diameter 26.

Loc. Kalfu-Tamaskie.
Collector. Colonel Elliot.

## Panopaca sahariensis, sp. n. (Pl. V. fig. 10.)

Shell of transversely oval shape, of greater length than height, with anterior umbones and straight hinge-line. Valves inflated in the umbonal region, depressed posteriorly, and with nearly parallel dorsal and ventral margins. Sculpture consisting of rounded, equidistant costæ, separated by fairly wide and shallow grooves.

Dimensions. Umbono-ventral 26 mm ; antero-posterior (approximate) 50 mm . ; diameter 27.

Shell related to Mya intermedia of James Sowerby, occurring in the Eocene deposits of Britain and Europe, but appearing to differ chiefly in its lesser umbono-ventral measurement, and the possession of nearly parallel dorsal and ventral margins. The sculpture is very similar, the broad equidistant sulcations being clearly expressed. The dorsoposterior part of the valve shows an oblique depression extending from the umbonal region to the outer margin, whilst a second specimen proves that the anterior region was very short.

T'wo fragmentary natural casts with closed valves represent this form; that figured and described is imperfect anteriorly.

Loc. Kalfu-Tamaskie.
Collector. Colonel Elliot.

## Gastropoda.

Calyptrea nigeriensis, sp.n. (Pl. V. fig. 3.)
This form of Calyptrea is represented by a natural lime-stone-cast exhibiting fairly good external characters. It is a subglobular form, and possesses four slightly rounded, depressed whorls, the penultimate being of considerable depth $(17 \mathrm{~mm}$.$) in front, whilst the last is fractured and imperfect.$ The surface of the later whorls is ornamented with numerous straight, longitudinal, radial riblets, which are fine at first, but which afterwards become coarser, being thickest near the slightly impressed suture. These radial lines show certain obscure asperities which indicate the former presence of minute spines. 'The apical surface is apparently smooth.

Dimensions. Summit to margin of basal fracture 44 mm .; transverse diameter 50 mm .

This species appears to show a relationship to $C$. aperta of Solander, from the European Eocenes. It is, however, of less conical form, more spreading and depressed in its volutions, and with a more regular and generally coarser sculpture; the sculpture of $C$. aperta being of a vermicular character, and considerably more mintite in the disposition of its spines. On the matrix of this specimen occurs the remnant of an Echinoid plate, with some prominent tubercles which may represent the genus Rhabdocidaris referred to in De Lapparent's account of fossils from this area of Africa.

Loc. Kalfu-Tamaskie.
Collector. Colonel Elliot.

## Volutilithes cithara, Lamarck. (Pl. V. fig. 2.)

Voluta cithara, Lamarck, Hist. Nat. Anim. sans Vert. 182.2, vol. vii. p. 348; Deshayes, Desc. Coq. Foss. Paris, 1835̃, vol. ii. pl. xc. figs. 11, 12, p. 681 ; J. de C. Sowerby, Mineral Conchology, 1843, vol. vii. pl. 620., figs. 1, 2, 3 ; id. Dixon's 'Sussex,' 1850, pl. v. fig. 17, p. 106 ; F. E. Edwards, Mon. Pal. Soc. 1854, pl. xxiii. fig. 6, p. 176 ; Archiac, Desc. Anim. Foss. Nummulitique l'Inde, 1854, pl. xxxii. figs. 4, 5, p. 325 ; Zittel, "Libysehen W ïste," Palæontographica, 1883 , vol. xxx. p. criii.
Volutilithes cithera, Cossmann, Ann. Soc. R. Mal. Belgique, 1889, vol. xxiv. p. 195.
Consists of a limestone-cast of a small compressed example of a Volutiform shell, resembling in every way the $V$. cithara figured by Archiac from India, especially his figure 4, which is likewise a cast. It exhubits the distant longitudinal costæ with the smooth concave interspaces so characteristic of the species. The specimen is very much worn, so that no oblique spiral lines are observable at the anterior end. This
is a frequently found Eocene shell of England, Europe, Egypt, and India.

Dimensions. Length 35 mm. ; max. diameter 19.
Loc. Garadimi.
Collector. Captain Lelean.
Rostellaria cf. goniophora, Bellardi. (Pl. V. fig. 1.)
Fusus goniophorus, Bellardi, Mem. R. Accad. Sci. Torino, 1854, ser. 2, vol. xv. pl. i. fig. 8, p. 181.
Rostellaria goniophora, Blanckenhorn, Zeitsch. Deutsch. geol. Ges. 1900 , vol. lii. p. 446.

A rather compressed limestone-cast of what appears to be an example of Bellardi's Fusus goniophorus, from the Nummulitic rocks of Egypt. It comprises three whorls, the carlier part of the spire being absent, on two at least of which can be traced an obtuse posterior angulation beneath the suture. The front or apertural view exhibits the presence of a sharp carination extending from the posterior corner of the mouth, beneath which on the base of the shell occur rather distant, elevated spiral lines. No anterior canal is preserved, the specimen showing a fractured surface where that would originally have been situated. The dorsal aspect closely resembles Bellardi's figure ; and it is interesting, further, to note that Dr. Blanckenhorn records the species from the Alectryonia Clot-Beyi beds ( $=$ Lutetian) of the Fajun district of Egypt.

Dimensions. Maximum diameter 25 mm .
Loc. Garadimi.
Collector. Captain Lelean.

## Turritella cf. agyptiaca, Mayer-Eymar.

Turritella ayyptzaca, Mayer-Eymar, Journ. Conchyl. [Paris] 1895, pl. ii. fig. 2, p. 41.
'Two fragmentary specimens most probably related to this species. The best preserved exhibits the basal whorl and part of the penultimate separated by a fairly deep suture. This last whorl bears three equidistant carinations and a more obtuse one on the anterior margin formed of two spiral lines very close to each other. Obscure spiral lines are also present on the areas between the carina. According to Mayer-Eymar, T. cegyptiaca ranges from Upper Cretaceous rocks (Garumnian) to Lower Tertiary (Londonian).

Dimensions of last whorl. Height 19 min ; width 13 mm .
Loc. Garadimi.
Collector. Captain Lelean.

## Conus sp.

This specimen consists of a very rough natural cast of a Comus probably related to C. deperditus of Bruguiere, which is found in Eocene areas. It is of broadly conical form, exhibiting the last three volutions, and furnished with a suture which, in the cast, is deeply canaliculated or concave. There are no sculpture-markings of any kind preserved, nor is the anterior end complete, although its general contour and facies would suggest its connection with a form like C. deperditus.

Dimensions. Maximum diameter 35 mm .
Loc. Garadimi.
Collector. Captain Lelean.

## EXPLANATION OF PLATE V.

With the exception of figure 7 , all the figures are drawn of the natural size.

IX.-On new Species of Helicarion, Ariophanta, Eulota, Cyclotus (Eucyclotus), Lagochilus, and Diplommatina (Gastroptychia). By Hugh Fulton.

## Helicarion rugosa, sp. n.

Shell globosely depressed, thin, subtransparent, almost imperforate, light brown or horn-colour ; whorls 4, slightly convex, upper whorls smooth, the lower covered with rugose spiral stria, underside of last whorl getting smoother towards the umbilicus, carinated at the periphery; aperture suboval ; peristome simple.

Maj. diam. 40 ; alt. 23 mm.
Aperture: maj. diam. 23 ; alt. 20 mm .
Hab. N. Borneo (Waterstradt).
This large and striking form is quite distinct from any other species known to me.

## Arioplanta innata, sp.n.

Shell sinistral, depressed, broadly and deeply umbilicated, dark brown above, 1 ather light yellowish brown below, with a dark spiral band about 2 mm . wide at the periphery of last whorl, apex smooth, other whorls with somewhat distant arcuate rugose strite, underside of shell polished and smoother than upper part; whorls $5 \frac{1}{2}$, slightly convex, last rather sharply descending at about 3 mm . from the edge of the peristome; aperture suboval, whitish within, the colour-band showing through; peristome slightly thickened, basal portion narrowly expanded and triangularly dilated at point of insertion, middle of upper margin slightly bent downwards, margins joined by a thim transparent callus.

Maj. diam. 42 ; alt. 18 mm .
Hab. Yuman.
In form and coloration this species bears a superficial resemblance to the Javan species A. Rumphii, Busch, but is readily distinguished by its coarser sculpture and broadly open umbilicus.

## Eulota flexibilis, sp. n.

Shell subglobular, moderately umbilicated, very thin, dark green below, lighter with brownish tint on earlier whorls, with numerous oblique, somewhat conspicuous folds, traces of spiral lines under the lens; whorls barely 5, moderately convex; aperture rather dark within ; peristome flexible, very thin and acute, owing to which it bends inwards, triangularly expanded at point of insertion.

Maj. diam. 31 ; alt. 24 mm .
Hab.? Probably Saghalien Island (Keppel Coll.).
Very near E. lata, Gould, var. G'udeana, Pils., but has half a whorl less, is somewhat more depressed in form, and has less shelly matter in its composition, in fact hardly any; the whorls also increase more rapidly in size.

## Eulota (Euhadra) fiscina, sp. 1 .

Shell subglobular, moderately but deeply umbilicated, of a rather thin substance, light golden straw-colour, apical whorls darker, last whorl encircled at the periphery by a dark brown band, which is continued at the suture of the middle whorls, getting narrower as it ascends, covered with close, conspicuous, raised, oblique strix, with numerous oblique folds on the last whorl, the place of a former peristome marked by a broad brown stripe, ormamented above and below with very
numerous impressed spiral lines, which can easily be seen without a lens; whorls $6 \frac{1}{2}$, moderately convex, slightly depressed at suture of lower whorls, last descending; aperture subcircular, almost white within, outer band showing clearly through; peristome moderately expanded, margins brown.

Maj. diam. 34 ; alt. 27 mm .
Hab.? Probably Saghalien Island (Keppel Coll.).
In form and coloration somewhat similar to E. miranda, Smith, but more globose, and readily separated by its spiral sculpture. I had thought that it might possibly be a large form of $E$. serotina, Ad.; but Mr. G. K. Gude, who possesses a co-type of that species, kindly informs me that $E$. serotinx, besides being smaller, is much smoother, its spiral sculpture is much weaker and the lines closer together.

> Cyclotus (Eucyclotus) amabilis, sp. n.

Shell broadly umbilicated, depressed, solid, finely obliquely striated, some of the strix very conspicuous on underside of last half-whorl, yellowish brown, ornamented with short and rather distant narrow stripes (sometimes zigzag) of darker brown, these becoming obsolete on the last half-whorl ; spire slightly raised; whorls 5, convex, regularly increasing; aperture circular, whitish ; peristome double at outer, single at columellar portion, the outer peristome being expanded at the upper part and forming a short canal at its termination; operculum shelly, slightly concave, having 12 whorls.

Maj. diam. 26 ; alt. 12 mm.
Hab. N. Borneo (Waterstradt).
Chiefly distinguished from other species known to me by its large oblique aperture and well-produced Pterocyclus-like channel at upper junction of the peristome.

## Lagochilus proprium, sp. n.

Shell moderately umbilicated, globosely turbinate, yeillowish brown, ornamented on last two whorls with narrow, oblique, yellowish stripes; whorls $5 \frac{1}{2}$, very convex, finely striated, with four spiral threads or liree on last whorl, the upper one ascending the penultimate whorl; aperture circular ; peristome narrowly expanded, operculum normal.

Maj. diam. $6 \frac{3}{4}$; alt. 7 mm .
Hab. Borneo (Keppel Coll.).
At first I thought that this characteristic Lagochilus might be L. Keppeli, Godw.-Aust., but that species has more spiral threals and the peristome is more expanded. Some specimens; are of a uniform rather light yellowish-brown colsur, the stripes being absent.

## Diplommatina (Gastroptychia) electa, sp. n.

Shell sinistral, oblong-conic, greyish brown, moderately solid, ornamented by fine and close-set oblique strix; whorls 8, distinctly convex, regularly increasing ; aperture subovate, orange within; peristome double, the imner part exserted forward and the outer expanded, orange-colour ; columella tortuous, expanded at point of insertion, bearing a distinct plait on the lower part, which is continued within the aperture; two interior plaits or callosities are seen from the exterior, more plainly if the shell be wetted, the first appears as a perpendicular orange-coloured line commencing just above the point of insertion of columella and directed upwards, the other runs near to and parallel with the suture, and is situated just to the right of the aperture.

Maj. diam. $3 \frac{1}{2}$; alt. $6 \frac{1}{2} \mathrm{~mm}$.
Ilab. N. Borneo (Waterstradt).
This distinct species can easily be separated from D.adversus, Ad., by its more regular form, stronger sculpture, and more numerous whorls.
X.-On Chelonethi, chiefly from the Australian Region, in the Collection of the British Museum, with Observations on the "Coxal Sac" and on some Cases of Abnormal Segmentation. By C. J. With, Copenhagen.

## [Plates VI.-X.]

The observations included in this paper were all made on material belonging to the British Musem (Natural History). For the liberality with which the collections of Chelonethi were handed over to me I tender to the Director, Professor E. Ray Lankester, my best thanks. I am also grateful to Dr. W. T. Calman, because he assisted me with his extensive knowledge of literature, as well as to several members of the entomological staff, especially Col. Bingham, by whose kindness it became possible for me to investigate some specimens of Hymenoptera which were remarkable on account of their abnormal segmentation.

In the following pages I have first given a revision of the Australian species of Chelifer, because I had oceasion to examine a good many of the described species, and among them several typical specimens. In addition to these, I have
described or redescribed several species from other parts of the world, which seemed to me of special interest. Owing to the fact that I have taken characters from several organs -for instance, the legs and antennæ-hitherto more or less ignored by students of this group, it has been necessary to give rather long descriptions. In this paper I have no occasion to discuss the generic value of several of these characters, but refer to another paper which I hope to publish shortly. The same is the case with my studies on the coxal sac of Ch. socotrensis, sp. n., of which I have given a short description without comparison with the corresponding organ in other nearly related forms. With regard to the ecdysis, about which scarcely anything is found in the literature, I refer to the description of Ch. sculpturatus, Lewis (p. 122).

Some cases of abnormal segmentation in Ch. sculpturatus, Lewis, and Ch. javamus, Thor., described in the third part of this paper, and compared with similar cases in other Arthropods and Amelids, are, perhaps, of more general interest.

## I.-Systematic Part.

The following synopsis of the species of the genus Chelifer from the Australian Region, as well as of those from other parts of the world described in this paper, has been difficult to get into proper shape on account of the very incomplete descriptions of many species ; but, nevertheless, I hope that it will be fairly easy to identify most of the species by its help:-

```
a. Femora and tibiæ of the palps beset with large
    subconical tubercles.
    sculpturatus, Lewis.
b. Femora and tibize of the palps without any
    tubercles.
    a}\mp@subsup{a}{}{2}\mathrm{ . Femora of the palps at least three times
        longer than bruad. Fingers shorter than
        hand.
        a}\mp@subsup{a}{}{2}\mathrm{ . Trochanter of the palps distinctly broader
            than the femur.
        a}\mp@subsup{}{}{3}\mathrm{ . Eyes distinct. Abdominal and tarsal
            "tactile" hairs present.
            a}\mp@subsup{a}{}{4}\mathrm{ . Hairs partly clavate; skin sha-
                        greened
                            laysmensis, Sim.*
            b}\mathrm{ . Hairs pointed; skin almost smooth;
                        tarsus iv. with median "tactile"
                        hair and only 1.5 times longer than
                        femur iv. is high. Claws with
```

[^25]anterior tooth; fingers without accessory teeth<br>bifissus, Sim.

$b^{3}$. Eyes or ocular spots not present. Abdominal and tarsal "tactile" hairs wanting; tarsus iv. at least twice longer than the femur is high; claws without teeth; fingers with accessory teeth.
$a^{3}$. Femora of the palps without stalk, gradually widened out towards the extremity, four times longer than broad; inner margin of hand only slightly convex
hawaïensis, Sim.
pacificus, sp. n.
$b^{2}$. Trochanter of the palps not broader than femur. Femora stalked and not gradually widened out distally.
$a^{6}$. Eyes distinct; hairs of tergites clavate, not pointed; two transverse grooves; abdominal "tactile" hairs present.
$\boldsymbol{a}^{7}$. Skin shagreened; hand a little longer than fingers
laysanensis, Sim.*
$b^{7}$. Skin with low granules; hand much longer than fingers; tarsus iv. with terminal tactile hair and twice longer than the femur is high ; claws with anterior tooth
socutrensis, sp. n.
$b^{6}$. Eyes wanting ; hairs pointed ; no transverse grooves (?) ; hand much longer than fingers
megasoma, Daday.*
aquatorialis, Daday.
$b^{10}$. Hand not or only slightly (1.2) longer than fingers.
$a^{11}$. Finger longer than the hand is high; inner margin of hand not semicircular
scorpioides, IIerm. (?).
australiensis, sp. 11.

```
    b}\mathrm{ . Nairs of palps not clavate, but obtuse;
        femur distinctly longer than tibia;
        fingers a little shorter than hand and
        longer than the hand is high; tarsusiv.
        with median "tactile" hair; fingers
        with accessory teetk; lower tubercle
        of trochanter subconical
l
    a}\mp@subsup{}{}{12}\mathrm{ . Tubercles of the trochanter exceed-
        ingly long, at least one subconical;
        ocular spots; no transverse grooves;
        tarsus iv. with basal "tactile" hair
        and ouly 1.3 longer than the femur is
        high
b}\mp@subsup{}{}{12}\mathrm{ . Tubercles of the trochanter moderate
        or wanting.
    a}\mp@subsup{}{}{13}\mathrm{ . At least one transverse groove.
        a}\mp@subsup{}{}{14}\mathrm{ . Fingers much shorter than hand,
            not longer than the hand is high;
                ocular spots ...................
        b}\mp@subsup{}{}{14}\mathrm{ . Fingers almost as long as hand.
            a}\mp@subsup{}{}{15}\mathrm{ . Ocular spots wanting; fingers
            scarcely shorter than hand,
                with accessory teeth; tarsusiv.
                with median " tactile" hair ..
            b}\mp@subsup{}{}{15}\mathrm{ . Ocular spots present; tingers
                distinctly shorter than hand..
                distinctly shorter than hand..
            tinctly shorter than hand.
            a}\mp@subsup{}{}{16}\mathrm{ . Femora more than twice longer
                than broad; no ocular spots ....
                b}\mp@subsup{}{}{16}\mathrm{ . Femora of the palps only twice
                longer than broad.
            a}\mp@subsup{}{}{l7}\mathrm{ . Hairs of the tergites within a
                distinct white spot
            b}\mp@subsup{}{}{17}\mathrm{ . Hairs not situated in distinct
                white spots; hand higher than
                broad, distinctly louger than
                    fingers
    pallipes, White.
                            pygmeus, Keys.
                                    ramosus, Keys.
                                    megasoma, Daday.*
                                    punctatus, Keys.
                            brevidigitatus, Keys.
    equester, sp.n.
```

## Geographical Distribution.

The following species of Pseudoscorpiones are known from the Australian Region :-

From the Australian continent: Chelifer australiensis, sp. n.; Ch. brevidigitatus, Keys.; Ch. brevispinosus, Keys.; Ch. punctatus, Keys. ; Ch. pyymeus, Keys. ; Ch. ramosus, Keys. ; Olpium longiventer, Keys.

From New Guinea : Chelifer equatorialis, Dad.; Ch. meyasoma, Dad.; Ch. scorpioides, Herm.; Chthonius Wiassicsi, Dad.; Ideobisium bipectinatum, Dad.

From New Zealand: Chelifer pallipes, White.
From New Caledonia: Obisium antipodum, Sim. Ann. \& Mag. N. Hist. Ser. 7. Vol. xv. 7

From Funafuti : Garypus longidigitatus, Rainbor: Obisium antipodum, Sim. (?).

From Sandwich Islands: Ch.bifissus, Sim. (?) ; Ch. havaiiensis, Sim.; Ch. pacificus, sp. n.; Garypus personatus, Sim.

From Laysan: Ch. laysanensis, Sim.
I will prove later on ( $\mathbf{p} .100$ ) that it is doubtful if the specimens of Ch. bifissus, Sim., from Sumatra and Hawaii really are the same species. The occurrence of Ch . scorpioides, Herm. (Daday, 4, p. 477), in New Guinea and Obisium antipodum, Sim. (Kainbow, 5, p. 108), at Funafuti cannot be accepted without further investigation. Olpium (Ampliolpium) longiventer, Keys., has been found on Hawaii and Funafuti according to Simon (9, p. 519) and Pocock (6, p. 321). I have examined the original specimens determined by these two naturalists, and a detailed investigation has convinced me that they are different from each other as well as from Olpium longiventer, Keys., and are most naturally referred to the genus Garypinus, Daday.

## Description of Species.

Under the heading "Measurements" in the following descriptions the first figure in each case gives the greatest length of the organ referred to. The figures within brackets give, in the case of the body, antennr, and palps, the breadth, or, when there are two figures, the greatest and least breadth, In the case of the legs the figures within brackets refer to the height of the joints.

Chelifer bifissus, Sim. (Pl. VI. figs $1 a-f$.)
1899. E. Simon, (8) p. 121.
1900. E. Simon, (9) p. 517.

Cephalothorax.-The eyes are indistinct. The cephalothorax, which is slightly longer than broad, possesses two rather indistinct transverse grooves, which are almost straight. The second thoracic tergite has an indistinct longitudinal line. The smooth and brilliant skin bears short and dentated hairs.

Abdomen.-The abdomen, which is longer than broad, has the tergites of almost equal length as well as breadth, with the exception of the first three, which are shorter. The sccond to the tenth sclerites are divided by an indistinct longitudiual line; the sclerites are almost smooth and with a hindmost marginal row of rather long hairs, with some distal tereth: the median segments possess at least one lateral hair
in front of the row on each side: the eleventh tergite bears one pair of "tactile" hairs in addition to the usual, which are long and placed without order. The lateral membranes are provided with densely placed longitudinal wrinkles or ridges. The fourth to the eleventh sternites are scarcely different from the corresponding tergites.

Antennce (fig. 1a). The Alagellum seems to consist of three almost simple hairs. The immovable finger bears on the inner dorsal margin some few minute teeth just behind the tip and farther backwards three larger. The galea (fig. la), which is scarcely longer than the distal curved hair, has at least six distal teeth. The servula is composed of about 25 rather high teeth, of which the basal one has the usual wide Hap.

Maxille.-The maxillæ, especially their distal portion, which is surrounded by a broad, exteriorly dentated lamina, are provided with many hairs.

Palps (fig. 1 b).-The palps are smooth, with the exception of the exterior surface of the trochanter. The hairs are rather scarce, slender, broken, and distally provided with a tooth ; they appear rather long, especially on the inner side. The fingers possess several tactile hairs. The trochanter, which has a rather long stalk, is distinctly longer than broad; its inner outline is evenly convex, its outer more abruptly so ; a slightly marked upper protuberance is present. The femur, which has a short rather distinct stalk, is not so broad as the trochanter; the inner surface is in the proximal half slightly convex and in the distal slightly concave; the outer side is evenly convex. The tibia, which has a moderately short but distinct stalk, is shorter than the femur and a little broader; the inner surface is beyond the notch, which marks off the stalk, moderately convex ; the stalk has exteriorly a basal prominence, which forms part of the articulation, and a distal low elevation separated from the former by a little notch; the joint proper is at first almost straight and then distinctly convex. The hand, which is almost as long as but broader than the tibia, is evenly convex both inwards and outwards; it is broader than high and distinctly longer than the fingers, which scarcely gape when closed.

Coxce.-The third and the second pairs of conre are of almost equal breadth and widened out distally; the fourth pair, which is almost as broad basally as distally, is as bruad as the third is at the end; the hinder margin is almost straight and forms an obtuse rounded angle with the inner.

Legs (figs. l c-f).-The scarce hairs of the legs are almost all provided with one or two minute teeth distalls, and
broken ; the hairs of the ventral side are the longer; near the tip of the tarsus some simple hairs are found. The dorsal "tactile" hair of the fourth tarsi is nearer to the base than to the tip and scareely shorter than the tarsus; dorsally near to the base of the claws there is a pair of curious hairs. The posterior hair of tarsus iv. (fig. $1 f$ ) is rather slender, and becones suddenly thimer near the tip, where it is bifurcate; the lower branch is very slender, much the longest, and almost straight, while the upper is very short, most similar to a tooth (fig. $1 f$ ). The anterior hair is distinctly curved, rather suddenly pointed, and with a little dorsal tooth near the tip; the shaje of this hair is consequently very similar to that found in Chelifer javanus, Thor., \&c. The posterior hair of the first pair of tarsi is comparatively shorter than that of the fourth pair, and has the lower branch slightly curved downwards (fig. $1 e$ ) as in Ch. socotrensis. 'The anterior hair is moderately long and thick, and its distal enlarged portion bears at least three tecth. The claws possess a well-developed anterior tooth near the tip. The areola is shorter than the claws. The legs are short and rather stout ; the trochantin of the first pair is sery long. The tibia, which is moderately eularged distally, is distinctly longer than the slightly pointed tarsus; the tarsus of the fourth pairs is comparatively much longer than the tarsus of the first.

Colour.-The palps are reddish brown; the cephalothorax is brilliant dark brown; the abdominal tergites are lighter brown and not brilliant. The coxre and the maxillie are reddish brown, lighter than the palps ; the legs are yellowish brown.

Measurements.-Cephalothorax $0560(0.520)$; abdomen $1.300(0.896) \mathrm{mm}$.

Palps: trochanter 0.308 ( 0.175 ); femur 0.550 ( 0.153 ) ; tibie $0.513(0.189)$; hand $0.495(0.257)$, height 0.225 ; fingers 0.380 mm .

Leg i.: femur 0.220 ( 0.120 ), trochantin $0 \cdot 180$; tibia $0.216(0.081)$; tarsus $0.171(0.053) \mathrm{mm}$.

Leg iv.: femur $0.405(0 \cdot 153)$, trochantin $0 \cdot 171$; tibia $0.315(0.099)$; tarsus $0.216(0.063) \mathrm{mm}$.

Material, Remarks.-I have examined Simon's specimen from Olaa Hawaii. Mons. Simon writes:-"Le Ch. bifissus de Hawaii ne diffère en rien de celui de Sumatra." I have not had occasion to examine specimens from India, but, to judge from the description (8, p. 121), there are sone differences not quite without importance. I hope my description will make it possible for these who have specimens from the latter region to settle the question whether the Pacific and

Indian specimens belong to the same species. The characters in which the IIawaii specimen differs seem to be the following :-'The femur has a distinet stalk and is not so broad as the tibia; the hand is distinctly broader than the tibia and longer than the fingers; the galea is not simple.

## Chelifer australiensis, sp. n. (P1. VI. figs. 2a-g.)

Cephalothorax.-The eyes or ocular spots are missing. The ceplalothorax, which is as broad behind as it is long, becomes gradually narrow in front; the sides are straight or almost so, passing gradually into the front margin through a moderate convexity. Two dark rather distinct grooves or lines are present; the first is nearly straight, while the second is moderately curved forwards in the middle; both groores are, as usual, widened out laterally, showing that they represent the interarticular memhrane between the conver anterior and posterior margins of the adjacent somites. The skin is minutely granular and provided with moderately short clavate hairs, of which the most prominent are set in transterse rows along the front margin of the head and the hindmost margins of the two tergites.

Abdomen. - The abdomen, which is almost as broad as long, is broadest just behind the middle. The sclerites of the tergites are of almost equal breadtb, but the first three are, as usual, the shortest; the hiuder margin of each sclerite covers the front margin of the following. There seem to be traces of lateral projections or keels on the tergites. The sclerites, with the exception of the eleventh, are divided by a longitudinal line. Their granulation is better marked than that of the cephalothoras. About thirty rather short but distinctly clavate hairs are placed along the hiuder margin of the sclerites ; besides, a single hair is placed laterally in front of the row on all the tergites with the exception of the first three; the last ones have, in addition, a median pair in frout of the row. The hairs of the eleventh tergite are more irregularly arranged, and there seem to be no long, slender, pointed " tactile" hairs.

The lateral membranes possess densely placed undulated rilges. The fourth to the tenth sternites are, like the tergites, longitudinally divided; there is an increase in their length as well as in breadth from before backwards; the fourth is only half as broad and two thirds as long as the tenth sternite. The selerites bear hairs along their hinder margins, which are less distinctly clavate, especially those of the front sternites, where they are almost simple.

The sexual area consists of a semilunar hairy plate behind the genital openirg; in front and between the coxae there is a long and broad plate, which has the hindm. st margin sliglitly concave in the middle and is provided with many hairs ; laterally this plate is nearly connected with the corners of the posterior plate. In the area between the two plates several minute internal organs are seen through the integument (fig. $2 a$ a).

Antenne (fixs. $2 b-c$ ). -The flagellum (fig. $2 b$ ) is composed of four hairs, of which the foremost is the longest and the hindmost the sho rtest; they are all, especially the first and frourth, provided with a few teeth along the front margin. The four hairs are so closely connected at the base that probably they can only be moved together. The immorable finger bears about five teeth on the inner dorsal margin. A well-developed lamina exterior is present, as well as a lamina interior; the latter has a strongly folded plate-shaped portion which, when seen from below, covers the proximal dentated lobes. These lobes are placed obliquely to the longituoinal axis of the finger and directed forwards and downwards, each covering the hinder or basal margin of the following when seen in rentral view. The terminal spine, which seems to be placed on a slightly higher level than the lobes, has four teeth. The galea (fig. 2 $c$ ) is moderately long and slender and distally provided with fise teeth of different sizes. The servula exterior consists of about twenty-nine teeth, of which the median ones are the shortest and almost squarely truncate; the basal tooth is distinctly longer than the following, but only slightly enlarged distally; the last one is, again, a little more pointed and longer than the preceding.

Maxilla (fig. 2 a).-The maxillæ are granular and densely covered with rather long, slender, and distally dentated hairs. The lamina maxillaris is rather short.

Palps (figs. \& d-e). -The palps are indistinctly granular and everywhere beset with rather long, more or less clanate hairs; those of the fingers are pointed and amongst them are some tactile hairs. The trochanter, which is longer than broad, has a distinct stalk; the imner side has an almost semicircular outline from the stalk to near the tip; the outer side bears two bhunt prominences, of which the ventral and proximal is the longer, while the more dorsal is less marked. The femur, which is twice as long as brwad and broader than the trochanter, has a distinct stalk; this is most marked when seen from the side, because the upper surface is nuch more distinctly and suddenly raised than the exterior; the
inner side beyond the stalk is first moderately convex, and thereafter concave, while the outer side is regularly convex from the base to the tip. The tibia is as long as and distinctly broader than the femur, with a rather long and wellmarked stalk ; the inner side has first a deep notch to mark off the stalk, but is thereafter distinctly convex to near the tip, where a gentle concavity is found. The outer side, beyond the low basal protuberance which forms part of the articulation and the following low concavity of the stalk, is convex to near the tip, where a short low concavity is found. The hand (fgs. $2 d-e$ ), which is a little shorter than the tibia, but 14 times broader, is higher than broad, almost as high as long, and as high as the fingers are long. The curvature of the upper and inner surfaces, which are almost semicircular, is more marked than that of the lower and outer. The fingers, which gape slightly when closed, are prosided with the usual row of triangular teeth; the immovable finger bears also on the inner side four accessory teeth behind the distinctly hooked tip, and at some distance from these four others near the middle; on the outer side there are about nine of these teeth distally. The movable finger also bears a few on the inner and outer side near the tip.

Coxя (fig. 2a). - The first pair of coxæ are almost trapezoid ; the two following pairs are nearly triangular, as the iuner margin is very short ; the fourth pair have a similar shape, but the inner side is broader and the intero-posterior angle is obtuse and rounded.

Legs (figs. $2 f-g$ ). -The legs are moderately long and slender ; the hairs, especially the dorsal, are more or less enlarged distally, with a number of minute spines in all directions; this kind of hair is called clavate. The hairs on the rentral surface of the tarsi are almost simple; on each side of the claw there is a strongly curved hair corresponding to the bifurcated one found in Ch. cancroides, L. (cf. p. 120). The tarsus of the fourth pair of legs has some longer pointed hairs near the claws, but does not bear an inner "tactile" hair, in contrast to most other species with the exception of Ch. cimicoides, $\mathbf{F}$. The trochantin of the first pair with a well-marked stalk. The tibia, which is distinctly longer than the tarsus, is, like the latter, enlarged distally ; this difference in length between the two segments is, as usual, yet more marked on the fourth pair of legs.

Colour.-The maxillæ, palps, and cephalothorax are bright reddish brown (the two black transverse grooves excepted); the coxie and legs are lighter; the sclerites of the abdomen
are yellowish brown, but sometimes with a blackish shade; longitudinal line white.

Measurements.-Cephalothorax $15 \ddagger(1.54)$; abdomen 3.0 (2.38) mm.

Palps: trochanter 0.738 ( 0.590 ); femur $1 \cdot 40$ ( 0.644 ); tibia $1.481 .(0.228)$; hand $1.372(1.092)$, height 1.222 ; finger 1.232 mm .

Leg i.: femur $1 \cdot 12(0.308)$, trochantin 0.504 ; tibia 0.810 $(0 \cdot 196)$; tarsus $0728(0 \cdot 144) \mathrm{mm}$.

Leg iv. : femur 1 •84 ( $0 \cdot 392$ ), trochantin 0476 ; tibia $1.26(0.224)$; tarsus $0.868(0.171) \mathrm{mm}$.

Material \&c.-Two males of this species, which seem to be related to Ch. cimicoides, F., were collected by Mr. W. W. Froggart in Queensland.

## Chelifer hawaiiensis, E. S. (Pl. VI. fig. $3 a$; Pl. VII. figs. $1 a-f$.)

1900. E. Simon, (9) p. 518.

Ceplatothorax. - No eyes or ocular spots are visible. The cephalcthorax, which is a little longer than broad behind, is provided with two transverse grooves; these are slightly curved forwards, but the hinder is very indistinct. The skin is minutely granular; short, distally enlarged, and dentated hairs are abundant.

Abdomen.-The abdomen, which is distinctly longer than broad, has its tergites of almost equal breadth, with the exception of the first three, which are a little shorter; the front as well as the hinder margins of all the tergites are almost straight. The sclerites are indistinctly developed, as in so wany forms of Garypus, minutely granular, and provided with a row of short hairs along the hindmost margin. The sternites (iv.-xi.) are similar to the tergites. The genital area is rather indistinct in the type specimen, but seems to be similar to that of the other female. In this we observe a plate, the hindmost margin of which is strongly chitinized and with a row of hairs. Between this plate and the coxre we find a number of rather stout pointed hairs, articulated in deep and wide cavities.

Antenne.--The gralea is broken distally, but seems rather stout and with a short branch near the base.

Maxilla.-The maxilla are short and broad; they are shagreened latcrally, but smooth in the middle, and provided with a few short pointed hairs.

Palps (fig. $1 a$ ).-Only the exterior surface of the tro-
chanter and the interior of the femur and tibia are minutely shagreened; the low flat granules of the hand are very indistinct. Rather short and more or less dentated hairs are abundant everywhere; those of the fingers, which, besides, bear tactile hairs, are more slender and simpler. The arrangement of the tactile hairs (PI. VI. fig. $3 a$ ) seems to be similar in the two specimens: most conspicuous are two placed very near to each other at the base of both fingers exteriorly ; two others are placed more distally on each finger. Interiorly there are two close to each other near the base and a single one distally; dorsally there are a few. The trochanter, which has a long stalk, is distinctly longer than broad ; its imer surface is evenly convex to near the tip; the outer is suddenly convex, almost similar to a protuberance; under this and separated from it by a longitudinal depression there is a less-marked more even convexity, which is, perhaps, the real exterior outline of the joint. The femur has no marked stalk, is narrower than the trochanter, and about 4.5 times longer than broad distally ; it is gradually enlarged distally; the inner surface is, after a shallow notch and low elevation, almost straight; the outer is, beyoud a basal short concarity, almost straight proximally, but distinctly convex distally. The tibia, which has a rather short and not very well-marked stalk, is a little shorter and broader than the femur ; the imner surface, beyond the distinct lasal noteh, is almost straight; the outer has a well-marked basal prominence and a low elevation where the stalk passes into the joint proper; between these two there is a shallow notch; the outline, beyond the above-mentioned elevation, is almost straight and at last convex. The hand, which is as long as but only $1 \cdot 16$ broader than the tibia, is slightly convex materiorly, but almost straight exteriorly; it is 2.5 longer than broad, a little broader than it is high, and a trifle longer than the fingers, which gape slightly when closed. Besides the usual marginal row of tecth, which are rounded basally and conical distally, the fingers bear accessory tecth, the number and position of which differ in the two specimens examined. The one (Pl. VI. fig. $3 a, a$ ) had along the imer' side of the immovable finger eight teeth, of which the first three near the middle were divided distally; the movable finger possesses four inside. Exteriorly the immovable finger bears about nine accessory teeth and the movable four; all these are placed more or less near to the middle. In addition to these teeth we find a number of organs (fig. $3 a, a)$ which scem to bear some similarity to those described by Hansen ( 5 , p. 217). The other specimen differs from that deseribed
in minor details with regard to the number and arrangement of these teeth.

Coce.- The enxæ are very similar to those of Ch. australiensis, sp. n. (PI. VI. fig. $2 a)$, but are more slender; the third is not so broad distally as the second, and the fourth pair not enlarged towards the extremity.

Legs (figs. 1 b-d). -The rather short hairs of the first pair of legs are almost simple ventrally, but with a distal tooth, or broken dorsally; the hairs of the fourth pair of legs, at least along the dorsal side of the femur and tibia, are distinctly enlarged distally and provided with a distal and some lateral spines. The dorsal "tactile" hair of the fourth tarsus is wanting, unless a rather short, pointed, and simple one near the base of the claws represents it; I was not able to make out whether this hair was paired or single. The hairs which are found on each side near the base of the claws are moderately curved and without a distinct tooth distally (fig. $1 d$ ). The claws are very slender and longer than the areola. The legs are exccedingly long and slender. The trochantin of the first pair of legs (fig. $1 b$ ) is rather short; the femur is much longer ( $5 \cdot 3$ ) than high; the tibia, which is moderately enlarged distally, is a tritte longer than the tarsus. The trochanter of the fourth pair of legs (fig. l $c$ ) is almost twice as long as high; the femur is much ( $4 \cdot 3$ ) longer than high, and only 1.7 times longer than the tarsus; the tibia is distinctly longer than the tarsus, which is $2 \cdot 6$ longer than the femur is high.

Colour.--The palps, maxillæ, and cephalothorax are pale yellowish brown; the femur and tibia are lighter than the other joints of the palps. The abdomen is brownish in the one specimen with indistinct darker spots, in the other more yellowish with more distinct dark selerites. The coxae and legs are yellowish.

Measurements.-Cephalothorax $1.4(1 \cdot 3)$; abdomen 3.6 (2.0) mm .

Palps: trochanter $0.700(0.420)$; femur 1.624 (0.344); tibia $1.316(0.364)$; hand $1.344(0.53: 2)$, height 0.504 ; fingers 1.092 mm .

Leg i.: femur $0 \cdot 960(0 \cdot 180)$, trochantin $0.356(0 \cdot 204)$; tibia $0.616(0.130)$; tarsus $0.588(0.100) \mathrm{mm}$.

Leg iv.: femur $1.134(0.252)$, trochantin 0.392 ; tibia $0.840(0.150)$; tarsus $0.672(0.120) \mathrm{mm}$.

Material.-I have examined two females: the one, which is probably Simon's androtype, is dilated by eggs; the other, which has a small bundle of eggs attached to the genital area,
has a smaller abdomen, with more distinct colours and slightly longer palps.

## Variety.

Cephalothorax.-The transverse grooves are very indistinct, but the granulation much better marked.

Abdomen. - The first three very short tergites have the hindmost margin distinctly convex and the foremost concave ; the median tergites have both margins more or less straight, while the last ones have the anterior margin convex and the posterior concave. The sclerites are well developed and divided by a broad longitudinal line where the skin is distinctly reticulated. The hairs are evidently clavate; the eleventh tergite possesses a number of very small round spots similar to those found in Ch. equester, sp. n. (cf. p. 124). The genital area seems to be different from that found in the typical specimen.

Antenne (Pl. VII. fig. 1 e).-The flagellum is composed of four hairs, of which the anterior longer one bears many marginal teeth, while the second has only a few. The lamina interior has at least three distal lobes with very long teeth; the terminal spine is shorter, distinctly hooked, and provided with six long teeth. Tie galea (fig. le) has some few teeth distally and is a little longer than the hair at its base. The teeth of the serrula (fig. le) are high, the terminal is pointed, and the basal is only slightly enlarged distally.

Maxillce.-The maxillæ are not only beset with granules laterally, but bear also some larger protuberances.

Palps.-The granulation, especially that of the hand, is more pronounced, and the hairs, especially those from the inner surface of the femur, are distinctly clavate. The tactile hairs of the fingers scem to be arranged as described (p. 105). The j ;ints are comparatively shorter and broader ; this difference is especially marked on the hand, which is $1 \cdot 6$ times broader than the tibia and only $2 \cdot 1$ times longer than broad; the margins, especially the inner, are a little more convex ; the number of secondary teeth of the fingers is very different; interiorly I was not able to discover any, but exteriorly the immorable finger bears at least six and the movable four.

Leys.-The hairs of the legs are more distinctly clavate ; the lateral hairs near the base of the claws are more curved (fig. lf ). The legs are comparatively shorter and higherfor instance, the femur of the first pair of legs is only 4.4 longer than high.

Colour.-The palps and maxillæ are reddish brown; the
ecphalothorax is a little paler ; the abdominal sclerites are brown, with a white and a black spot and divided by a broad, white longitudinal line.

Measurements.-Cephalothorax 1.34. (1•12); abdomen $2128(1.820) \mathrm{mm}$.

Palps: trochanter 0.616 ( 0.392 ) ; femur $1.344(0.300)$; tibia $1.1 \% 6(0.320)$; hand $1.092(0.504)$, height 0.476 ; fingers 0.980 mm .

Leg i.: femur $0.786(0 \cdot 178)$, trochantin 0.308 ; tibia 0.532 $(0.130)$; tarsus $0.476(0.084) \mathrm{mm}$.

Leg iv. : femur $0.972(0.25 \%)$, trochantin 0.364 ; tibia 0.756 $(0 \cdot 1 \cdot 10)$; tarsus $0.616(0 \cdot 112) \mathrm{mm}$.

Material.-I have examined one specimen (ㅇ) of the variety from Kanai, one of the most western islauds of the Sandwich Archipelago.

Remarks.-As I have only seen three specimens of this species, I have not thought it advisable to establish the variety as a new species; but, on the other hand, as the differences seem to be well marked and as the specimen is from another locality, I think that the description of the differences will be of value to fature workers. It would be interesting to investigate the relation between the geographical distribution and the variations.

## Chelifer pacificus, sp. n. (Pl. VII. fig. 2 a.)

Cephalothorax.-No eyes or ocular spots a e present. The cephatuthorax is a little longer than broad ; it is more distinctly produced in front and with a better-marked median incision than Ch. hawaiensis; the almost straight transverse grooves are indistinct; the skin is distinctly but minutely gramular and the distinctly clavate hairs are almost as long as broad.

Abdomen.-The abdomen is distinctly longer than broad; the tergites have their selerites poorly developed, and the finst three are only in a slight degree shorter than the other; both the anterior and the $p$ sterior margins are almost straight. The whole surface of the tergites, including the indistinct longitudinal line in the middle, is shagreened. Eight transveise rows of clavate hairs are present as well as some few hairs (lateral) in front of the row on the median segments. Genital area scarcely different from that found in (h. huwuiiensis, Sim.

Anterne.-The flagellum consists of four hairs. The lamina interior possesses three or four lobes, the teeth of which are comparatively short; the terminal spine, which is
rather thick and suddenly pointed, is not crooked and is provided with five teeth. The galea, which is rather slender and a little longer than the hair at its base, is provided with five teeth distally. The $2 l$ teeth of the servind are moderately long; the basal one is longer and is slightly and erenly enlarged towards the extremity.

Maxilla.--The maxillæ are shagreened laterally.
Palps (fig. 2a).-The palps are minutely granular, especially the inner surface of the joints, with the exception of the trochanter, which is shagreened posteriorly. The hairs are rather short, widened out and spinous distally. The number and the arrangement of the tactile hairs of the fingers are as in Ch. hawaiensis, Sim. The trochanter, which is longer than broad and distinctly stalked, is strongly but evenly convex interiorly; the exterior outline is more abruptly convex, and the distinction between the upper prominence and the lower, which passes into the stalk, is well marked. The femur, which has a short stalk and is narrower than the trochanter, is 3.6 times longer than broad ; it is not gradually and distinctly widened out towards the extremity ; the inner outline is almost straight ; the convexity of the outer side begins just beyond the notch which marks off the stalk. The tibia, which has a short, not very well-marked stalk, is distinctly shorter and a little broader than the femur; both the inner and the outer margins are slightly convex. The hand, which is as long as, but 1.6 times broader than, the tibia, is distinctly convex both interiorly and exteriorly ; it is 1.9 times longer than broad, a little broader than high, and scarcely longer than the fingers, which do not gape when closed. In position and number the accessory teeth differ from those described under Ch. hawaïensis (p. 105) ; the immovable finger has along the inner margin at least three distally, and the movable one; the former has at least five exteriorly.

Legs.-The hairs of the ventral side are pointed, long, and more or less simple, while those of the dorsal side are shorter, widened out, and provided with teeth. The dorsal "tactile" hair of the fourth pair of tarsi is wanting. The lateral hairs near the base of the claws are slightly curved, very similar to those of Ch. hawaiiensis, Sim. (Pl. VII. fig. 1 d). The legs are moderately long; the trochanter of the fourth pair of legs is only $1 \cdot 5$ longer than high. The femora of the first as well as of the fourth pair are only four times longer than high ; the tibire are distinctly longer than the tarsi.

Colour.-The maxillæ and palps are brown, the former more brilliant; the cephalothoras and abdomen are brownish,
the latter more pale with darker spots; the coxæ and legs are yellowish brown.

Measurements.-Cephalothorax 1.036 (0.980) ; abdomen $2 \cdot 10(1 \cdot 316) \mathrm{mm}$.

Palps: trochanter 0.õ32 (0.336) ; femur 0.924 (0.260) ; tibia $0.832(0.280)$; hand $0.810(0.448)$, height 0.392 ; fingers 0.820 mm .

Leg i.: femur $0 \cdot 626$ ( $0 \cdot 155$ ), trochantin $0 \cdot 280(0 \cdot 175)$; tibia $0.420(0.112)$; tarsus $0.392(0.084) \mathrm{mm}$.

Leg iv.: femur $0.810(0.210)$, trochantin 0.300 ; tibia $0.616(0.120)$; tarsus $0.524(0110) \mathrm{mm}$.

Material.-I have examined a single female, probably from Hawaii ; it was mounted with Simon's original specimens of Ch. hawaiiensis, but evidently had not brea examined by him.

## Chelifer brevispinosus, Keys.

1885. Keyserling, (3) pp. 45-46, tab. iv. figs. 3-3 c.
ot. -The hand is scarcely as high as broad; the fingers gape distinctly when closed, especially distally, on account of a notch just behind the tip of the immovable finger; the inner margin at least of the fingers with a number of accessory tecth. The trochanter has posteriorly a lower, almost subconical projection and an upper, bigger and more rounded one. The legs are moderately short; the femur of the fourth pair is about $2 \cdot 5$ louger than high, and the tibia is much longer than the tarsus, which bears a tactile hair near the middle; the lateral hairs, near the base of the simple claws, are slightly curved and simple.

ㅇ․ - The fingers of the palps gape slightly.
I have examined Keyserling's original specimens.

## Chelifer pygmeus, Keys.

## 1885. Keyserling, (3) pp 49-50, tab. vi. figs. 8-8 b.

The last abdominal segment bears some "tactile" hairs. Trochanter with well-marked exterior tubereles. The fingers are almost as long as the broad hand, and bear a few accessory teeth on the distal half. The first pair of legs, the femur of which is 25 times longer than high, have the femur proper, tibia, and tarsus of almost equal length; the tarsus of the fourth pair of legs with a dorsal "tactile" hair in the basal half near the middle.

I have examined Keyserling's original specimens.

$$
\text { Chelifer pallipes, White *. (Pl. VII. figs. } 3 a-b .)
$$

1849. A. White, (1) p. 6.

Cephalothorax. - Two distinct eyes or ocular spots are present. The cephalothorax seems to be longer than broad behind, and becomes rather suddenly narrow in the anterion third. The head slopes towards the frout margin ; a distinct transverse groove, which is curved backwards in its whole length, is found near the middle; a second groove near the hindmost margin is indistinct and straight, as far as I could make out. The cephalothorax is every where distinctly granular.

Abdomen.-The granulation is less distinct and there seems to be a broad longitudinal line.

Antennce.-Tbe moderately long galea possesses at least four distal branches.

Palps (figs. $3 a-b$ ). -The palps appear quite polished ; but are nevertheless granular, the granules being so low and so near to each other that the whole surface appears to be covered with a minute mosaic. The hairs, especially those of the inner surface of the femur and tibia, are exceedingly long and pointed ; at least most of the hairs bear one terminal tooth; the hand has also tactile hairs in addition to the ordinary kinds. The palps are rather long and slender. The trochanter, which has a long stalk, is distinctly longer than broad ; the inner side is evenly convex, while the outer side is abruptly convex, but not so marked that we can speak of a lower posterior tubercle; the dorsal surface posteriorly and near the tip is slightly prominent like an upper tubercle. The femur, which has a short distinct stalk, is slightly broader than the trochanter and almost three times as long as broad; the inner side beyond the moderately concave stalk is slightly convex for a very short distance, but thereafter almost straight ; the outer side just beyond the stalk is rather suddenly, but more distally evenly convex. The tibia, which is both shorter and broader than the femur, has a long, wellmarked stalk; the inner side, after the deep notch of the stalk, is distinctly convex ; the outer side has a well-marked basal prominence and a rather low elevation separated from the former by a shallow notch before the moderate convoxity of the joint proper. The hand, which is almost as long as, but distinctly broader than, the tibia, is distinctly longer than, and as high as, the finger.

[^26]Coxce.-The fourth pair of coxæ is broad and widened out distally.

Leys.-The trochantin of the first pair of legs is short and its tibia is distinctly longer than the tarsus. The femur of the fourth pair seems to be exceedingly long and compressed; there docs not appear to be any "tactile" hair at the base of the tarsus.

Colour.- The cephalothorax, palps, and abdomen (according to White's description) are deep brown; the legs are pale. "The claws with a greenish hue...; abdominal segments edged wi h palish" (White, op. cit. p. 6).

Measurements.-Cephalothorax about 1 mm . long.
Palps: trochanter $0.600(0392)$; femur $1 \cdot 176(0 \cdot 420)$; tibia $1.092(0.476)$; hand $1.06 \pm(0.588)$, height $0.8 \% 4$; finger 0.784 mm .

Material.-I have examined White's typical specimen from New Zealand; it was driod and badly damaged. I hope it will be possible to recognize it from my description ; it would probably have been impossible to do so from the very short description given by White.

## Chelifer brevidigitatus, Keys.

1885. Keyserling, (3) pp. 48-49, tab. iv. figs. 6-6 c.

The tubercles of the trochanter of the palps are slightly marked; the femur is twice as long as broad; the hand is higher than broad and 14 longer than the fingers. The tarsi of the legs are much shorter than the tibie; the fourth pair has a dorsal "tactile" hair at the base; the lateral hairs near the base of the claws are strongly curved. The genital area is similar to that of Ch. birmanicus, Thor. The abdomen of the female is exceedingly long and slender.

I have examined Keyserling's original specimens.

## Chelifer socotrensis, sp. n. (Pl. VII. figs. $4 a-h$.)

ठ. Cephalothorax.-Two distinct eyes are present. The cephalothorax, which is slightly longer than broad, becomes gradually narrower towards the front maryin, which is bordered with a clear membrane. The anterior transverse groove is always straight in the middle, while the second is moderately curved forwards; the second tergite with a more or less indistinct longitudinal groove. The skin is everywhere gramular, with rather large and low gramules, which are always well separated from cach other. The short clavate hairs of the head aud first tergite are placed without order
everywhere, while a row of cighteen are placed along the hinder margin of the second tergite.

Abdomen.-The abdomen is rather slender, with all the dorsal selerites of almost equal breadth and length, with the exception of the first three, which are shorter; the tergites show scarcely any trace of lateral keels. All the tergites are, with the exception of the hindmost portion of the eleventh, divided by a distinct longitudinal line. The granules are perhaps lower than those of the eephalothoras and arranged in circles around the smooth spots which surround the lyriform fissures and the articulation of the more or less short, distally dentated hairs. These are situated in the following order :the first two tergites bear only a row of about eighteen hairs along the hindmost margin of the sclerite; this row is at the third tergite not quite straight, and each half has at least an imer and an outer hair in front of the row: the fourth to the eighth have, in addition to the hindmost marginal row, five hairs on each side in front of the row, placed in an irregular transverse row ; the order of these hairs is not quite symmetrical right and left; the right half of the sixth tergite possessed, for instance, in one specimen only four hairs. In the ninth and tenth sternites the two rows were not well marked off from each other; the light spots which surround the hairs are better marked in the anterior than in the posterior row ; the hairs of the hindmost tergites are longer, and the eleventh bears a pair of tactile hairs.

Stermites.-The fifth to the eleventh sternites are similar to the tergites and longitudinally divided like these; but the granulation is more obsolete, and the hairs, of which there is only one row along the hinder margin, are longer and more slender ; those of the anterior sternites are almost simple. The twelfth sternite seems to be missing, or, more correctly, it is fused with the elerenth ; for the latter has in the middle, just in front of the hindmost margin, a short transverse groove, partly cutting off its hindmost median portion. The fourth sternite has the anterior margin curved inwards. The genital area is composed of a rather short anterior plate and a longer posterior one; the former has many long slender hairs in the middle, while the latter has short hairs everywhere and covers a pair of "ram's-horn"-shaped organs (cf. Ch. cancroides, L.).

Antenne.-The flagellum seems to consist of only three hairs, of which the anterior longest one is armed with about nine teeth along the front margin, thus having similarity to a feather. 'The dorsal margin of the immovable finger possesses some tiny teeth just behind the tip, and thereafter five

Ann. \& Mag. N. llist. Ser. 7. Vol. xv.
larger ones; the first is the largest and the second is smaller than the third. The seruliform portion of the lamina interior consists of four dentated lobes and a terminal spine with six tecth. The yalea was broken. The servela exterior is composed of about 30 tecth, of which the basal one has a large distal flap.

Maxille.-The maxilla are of the nsual triangular shape, with a broad lamina dentated externally; they are granular along the sides, and hairy with short dentated hairs.

Palps (fig. 4a).-The palps are minutely granular everywhere above, with the exception of the hand, fingers, and stalks; the granulation is very indistinct beneath. Short, rather thick, distally dentated hairs are abmondant at all the joints, with the exception of the fingers, which bear rather long and slender hairs, besides the tactile hairs. There is no difference in length between the hairs on the imner and outer sides of the proximal joints. The trochanter, which is distinctly longer than broad, has a well-marked stalk; the inner margin is gradually convex, and so is the hinder ; the upper surface is posteriorly raised to a blunt tubercle. The femur, which is almost four times longer than broad and distinctly broader than the trochanter, has no well-marked stalk; its imer side is almost straight beyond a low short convexity near the base, while the hiuder is moderately convex. The tibia, which is as long as but broader than the femur, has a rather short but distinct stalk; its imer side is moderately convex after the decp notch of the stalk; the basal exterior prominence which forms part of the articulation is well marked, as well as the distal elevation of the stalk and the rather shallow notch between; the outline of the proper joint, which passes gradually into this elevation, is first straight and terminally convex. The hand, which is twice as long as broad and broader than the tibia, is 1.78 longer than the fingers; it is slightly longer than the cephatothorax and evenly convex both interiorly and exteriorly. The fingers do not gape when closed and are ouly $1 \cdot 25$ longer than the hand is broad.

Coxe (fig. 4b).-The coxa are scarcely different from those of Ch. australiensis, with the exception of the fourth pair, which is much broader than the third and only slightly widened out distally; the inner side is straight and makes an obtuse angle with the hinder margin, which is slightly concave and almost parallel with the conver front margin.

Coxal sac (figs. $4 c-f$ ).-Compare p. 135.
Legs (fig. 4 4 ). -The legs are comparatively long and slender. The hairs, which are found in numbers, are rather
short, thick, and provided with spines distally; those which are placed on the ventral surfaces of the tarsi are long, slender, and almost or completely simple; the trochanter bears also some longer and pointed hairs beneath. The dorsal "tactile" hair of the fourth pair of legs is placed near the tip. All the tarsi bear at least one hair, which is rather long and slender, on each side just above the base of the clars; besides these hairs there is on each side a differently shaped bifurcated hair. The posterior of these hairs, which scems to be alike on all the tarsi, is moderately long and divided near the tip into two branches, of which the lower and longer one is directed upwards and curved downwards, while the upper one is short and similar to a short tooth. The anterior hairhas the lower branch short and straight on at least the fourth pair ; that of the first pair of legs seems to bear several tiny teeth distally. The two long claws of the fourth pair of legs are as long as the areola and are armed with an anterior strong tooth. The anterior claw of the first pair is rather long and slender without any tooth, while the posterior is exceedingly long and slender, bearing an insignificant tooth inside. The claws of the second pair of legs bear comparatively well-developed teeth. The tibia of the first pair is only a trifle longer than the tarsus, which is broadest in the middle (fig. 4 g ), while the tibia of the fourth pair is considerably longer than the corresponding tarsus.

Colour. -The hand is reddish brown, the other joints, including the maxillæ, are lighter, and so is the head; the thorax and abdominal tergites are yellowish brown with the less chitinized portions paler; the ventral side and legs are yellowish.

Measurements.-Ccphalothorax $1 \cdot 26$ (1•134); abdomen $2 \cdot 156(1 \cdot 372) \mathrm{mm}$.

Palps: trochanter $0.730(0 \cdot 418)$; femur $1 \cdot 5056(0 \cdot 148)$; tibia $1 \cdot 540(0.476)$; hand $1 \cdot 40(0.630)$; fingers 0.790 mm .

Leg i. : femur 0.705 ( 0.252 ), trochantin $0420(0.270)$; tibia 0.565 ( 0.207 ) ; tarsus $0 \cdot 495(0 \cdot 140) \mathrm{mm}$.

Leg iv.: femur 1.232 ( 0.420 ), trochantin 0.40 ; tibia $0.952(0.252)$; tarsus 0.616 mm .

ㅇ. Cephatothorax.-The cephalothorax is as broad behind as it is long. The eyes and transverse grooves seem to be more distinct.

Abdomen.-The sclerites of the fourth sternite are short and widely separated from each other; many short pointed hairs along the hindmost margin of the sternite; the third sternite bears a similar row of hairs, and in front of the
genital opening there are a number of irregularly placed hairs.

Palps.-The palps are shorter and less powerful and there are small differences in the relative measurements. The dorsal prominence of the trochanter seems to be smaller, but more marked off; the hand is, compared with the tibia, both longer and broader than in the male; it is as high as broad.

Coxe.-The fourth pair of coxae has the hindmost margin straight and does not possess any coxal sac.

Leys.-The claws of the first (and probably also the sceond) pair of legs are different from those of the male; both claws bear teeth, but that of the posterior claw is placed under the summit, not anteriorly as usual. The first pair of legs differs from those of the male by the greater slenderness of the tibia and tarsus (fig. 4. $h$ ), as well as by the shape of the latter, which is of equal breadth throughout.

Colour.-The palps and maxillae are dark reddish brown, with the hands darker; the head and last abdominal tergites dark, more blackish brown, while the thoracic and first three abdominal tergites are lighter, the latter with white interarticulate membranes. The coxe and foremost part of the abdomen below are yellowish, while the hindmost portion is brownish.

Measurements.-Cephalothorax $1 \times 232(1: 260)$; abdomen $2.20(1.596) \mathrm{mm}$.

Palps: trochanter $0.660(0.364)$; femur $1.350(0 \cdot 40)$; tibia $1.354(0.455)$; hand $1.326(0.675)$, height 0.672 ; fingers 0.765 mm .

Leg i. : femur $0.765(0.213)$, trochantin $0.405(0 \cdot 265)$; tibia $0.600(0.168)$; tarsus $0.532(0.112) \mathrm{mm}$.

Material.-I have examined two males and one female, which are perhaps not quite full grown, from Socotra.

Remarks.-This species is very similar to Ch. Simoni, Bal., from Sierra Leone (ix, p. 529). The following are my reasons for establishing a new species:-Ch. Simoni, of which Balzan has examined full-grown specimens, is a much smaller species; its cephalothorax is distinctly longer than broad, both in male and female; the median abdominal tergites have only three hairs in front of the row along the hindmost margin of the selerite ; the fingers are distinetly longer than the hand is broad; the hand is shorter than the cephatothorax; the hairs along the imer side of the palps are distinctly longer than those along the outer.

## Chelifer sculpturatus, Lewis. (Pl. VIII. figs. $2 a-h$.

1903. Lewis, ( 56 ) pp. 497-498, pl. xxv.
q. Cephalothorax.-The two rather indistinct eyes or ocular spots are removed from the front margin a distance equal to their diameter. The cephalothorax, which is as broad behind as it is long, is only one-fourth as broad anteriorly as posteriorly; the front margin possesses a slight median incision. The foremost of the two rather shallow transverse grooves is straight or moderately curved backwards, while the hinder is distinctly curved forwards, and so is also the hindmost margin of the sccond tergite, which is so similar to an abdominal tergite that Lewis counted it amongst them.

The skin of the head, the first and in a less degree the second thoracic tergite are everywhere beset with very minute granules. The first thoracic tergite and at least the lindmost part of the head bear besides a number of low, round, and rather large granules and tubereles; the tergite possesses about fifty, while the head has comparatively few, which decrease in number as well as in size anteriorly. The cephalothorax bears some few rather slender, but blunt hairs, which, at least posteriorly, are placed each on its own tubercle. The granulation of the second tergite is so similar to that of the abdominal tergites that I can refer to the description of these.

Abdomen (fig. 2 a).-The abdomen, which is broader in the middle than it is long, is shaped similarly to that in Chiridium ; it slopes gradually from the middle towards the sides, and from the seventh tergite both forwards and backwards; the lateral outline is distinctly convex. The tergites slightly increase in length from the first towards the ninth, but much more in breadth towards the seventh. The second thoracie as well as the first ten abdominal tergites bear a pair of lateral, more or less marked projections.

Each abdominal tergite, with the exception of the eleventh, is divided into a posterior and an anterior portion by a transverse raised band or line, which is more zigzag than straight. These two portions are again subdivided into more or less round areas by short ridges, neither so raised nor so broad as the transverse band, between which and the margins they exteud. The depressed spots thus formed bear each a median knob, on which, at least sometimes, a short clarate hair is articulated: in each row about twenty of these areas are present; but they are sometimes rather indistinct, especially those of the anterior row, which are often covered
by the hindmost margin of the preceding tergite. The depressions described are minutely granular in a similar manner as is the head. The eleventh tergite is smooth.

Sternites.-The fifth to the elerenth sternites increase both in length and in breadth towards the middle. Both the fourth and the thind sternites are more or less covered by the fourth pair of coxæ. The sclerites of the former are distinctly narrower and only half as long as those of the fifth; the sclerite of the third sternite is almost a mere line. The sclerites of the sternites seem to be smooth, are provided with a hinder row of numerous, short, and almost simple hairs, and are divided by a narrow longitudinal line.

Antennc.- The minute organs of the small antenne were so badly preserved on the dried specimen at my disposal that I could not examine their structure in detail. The flagellum is composed of three (?) moderately long, curved, and slender hairs, of which the anterior one is provided with about five distal and marginal tecth. The margin of the immovable finger is provided with two minute dorsal teeth just behind the tip and more proximally five larger but of unequal size. A distinct but narrow lamina exterior is presest as well as a lamina interior, the serruliform distal portion of which seems to differ from that usually found in Chelifer. The galea is rather long and slender, distally provided with about seven short, blunt, and slightly curved tecth. The serrula exterior is similar to that found in Ch. claviger, Thor. ; it consists of about thirty, almost completely fused teeth, of which the basal one is the longest and widened out distally ; the terminal tooth is also comparatively long and slender.

Maxilla.-The maxille are placed on a level with the coxæ ; they are strongly raiscd in the middle, poisted in the front, and, at least in some specimens, with large granules laterally.

Palps (figs. $2 d-e$ ).-A minute granulation, similar to that of the head, seems to be wanting, but the whole surface is thickly studded with subconical tubercles; these tubercles are comparatively low on the trochanter, and almost wanting on the rentral side of the femur and tibia; some few low ones are found at the basal portion of the hand. Each tubercle bears a moderately long, stiff, and clarate hair near the tip ; the hairs of the hands, especially those of the inner side, are more slender, not clavate, but only provided with some few distal spines. This kind of hair is gradually merging into the simple and pointed hairs of the fingers, and is not to be confounded with tactile hairs. On the fingers of a cast skin (fig. 2 e) I observed in number a kind of organs
identical with or similar to those described by II. J. IIansen in Ch. cimicoides (15, p. 218, pl. v. fig. 14 a). Lach organ consists appareutly of a more or less irregularly shaped area with a marked round spot; they are either apart or more or less fused ; the area itself is in reality placed under the skin as a kind of chitinous sac. The immovable finger has iuwards two tactile hairs and about cight of these organs, placed in the proximal portion; the movable has none; the immorable as well as the movable possess outwards three tactile hairs and twelve organs. The trochanter, which is distinctly longer than broad, has a distinct stalk, which is enlarged basally; the interior margin is first suddenly and then gradually convex ; the exterior surface bears an upper and a lower projection, the latter is the longer, but neither the one nor the other is much more marked than one of the femoral tubercles. The femur, which is a little more than twice as long as broad, and distinctly broader than the trochanter, is provided with an exceedingly short stalk; the tubercles make it difficult to realize its shape, but the interior side scems to be almost straight, while the exterior is slightly convex. The tibia, which is slightly shorter but broader than the femur, has a moderately long, well-marked stalk, the axis of which forms an obtuse angle with the proper joint, and accordingly gives the tibia an inward direction. The interior side is moderately convex after the deep notch which marks it off from the stalk; the exterior side is almost straight beyond a sudden elevation which follows the stalk. The hand, which is slightly shorter and a little broader than the tibia, is as high as broad and longer than the fingers. The imner curvature is more marked than the outcr. The fingers (fig. $2 e$ ) gape widely when closed, because the lower margin of the immovalle finger is not straight, but with a distinct bend upwards behind the tip. The proximal tecth of the immovable finger are small and more or less rounded; those of the notch are extremely small, but they are followed by large and pointed oncs; the teeth of the movable finger are all more or less minute.

Coxe (fig. $2 f$ ). -The coxæ are on a level with the maxilla; the first pair is the shortest and trapezoid in shape; the second and third pairs are longer and enlarged distally, so that they become nearly triangular. The fourth pair is both broader and longer than the preceding ones (fig. 2 f ) ; they are much longer in front than behind; the hindmost shorter portion is distinguished from the anterior portion by a shallow groove ; both the interior and posterior margins with low concavitics. While the hairs of the first three pairs of
the coxe are short and spined, those of the fourth pair are longer and more slender.

Leys.-The ordinary hairs of the legs are rather short, stiff, and clavate; they are enlarged terminally and there provided with short branches in all directions. The ventral hairs of the tarsus are much longer and more slender than the dorsal ones; they are not simple, but spined distally. The claws seem never to bear teeth, but have an inner and outer bifureated hair near the base as in Ch. cancroides, L. (Pl. VIII. fig. $2 g$ ) ; this structure I have observed only in tarsi of a cast skin. The first legs have a very well-developed trochantin; the tibia is distiuctly enlarged distally and as long as the tarsus. The fourth legs have the tarsus enlarged distally and shorter than the tibia.

Colour.-The palps, maxillæ, head, and coxe are reddish brown, with a more or less pronounced purple shade. The raised band of the tergites is bright brown, while the depressed spots are more yellowish brown; sternites yellowish brown with a blackish shade. The whole dorsal surface is, when lighted, more or less metallic.

Measurements.-Cephalothorax $1 \cdot 4(0 \cdot 42-1 \cdot 68)$; abdomen $2 \cdot 1(2 \cdot 492) \mathrm{mm}$.

Palps: trochanter $0.644(0 \cdot 4.48)$; femur $1 \cdot 260(0 \cdot 540)$; tibia $1.148(0.540)$; hand $0.98: 2(0.576)$, lecight 0.550 ; fingers 0.812 mm .

Leg i.: femur 0.840 ( 0.308 ) ; trochantin 0.392 ; tibia $0.560(0.210)$; tarsus 0.560 mm .

Leg iv.: femur $1 \cdot 09 \pm(0.415)$; trochantin 0.336 ; tibia $0.728(0.250)$; tarsus 0.600 .

万. Cephalothorax.-The anterior groove is distinctly curved backwards. The granulations are less marked than in the female.

Abdomen.-The lateral projections of the tergites are much better marked than in the female. That of the second thoracic tergite is comparatively insignificant; those of the abdominal tergites attain their highest development in the sixth and seventh segments, and are there long, free, and similar to a keel, directed obliquely upwards, outwards, and backwards. The raised transverse bands, and especially the hindmost row of depressed spots, seem less marked than in the females.

The fourth sternite differs from the corresponding one in the female by being half as long and almost as broad as the fifth.

Genital area (fig. 2b).-The genital area is most similar to that found in Chelifer cancroides, L., and the species which are
nearly related to it. The anterior genital plate (fig. 2b, a), which is hairy in the middle, is situated between the coxie and the posterior plate ; it is well raised in the middle, prolonged backwards with a low concavity in the posterior margin; the lateral part gets rather suddenly and most distinctly shorter. The posterior genital plate, which is broad and long, is distinctly wider than long; its hinder margin is moderately raised backwards, the lateral margin, after a shallow concarity in which the first pair of stigmata (s.) is partly placed, is suddenly bent inwards, merging into the anterior margin. This is distinctly curved forwards on each side, and in the middle provided with a well-marked curvature, which fits into the convexity of the anterior plate. The median and anterior portion of this system is more raised than the lateral and posterior region when seen from below. From the front margin to the middle a longitudinal shallow depression extends, having a moderate clevation on each side, which cover the usual ram's-horn-shaped organs. The posterior part of this plate is distinguished from the anterior plate by an indistinct transverse groove (fig. 2b,g). Hairs are found at least along the front margin.

Palps (fig. 2 d).-The conical tubercles are larger than in the female. The palps are both longer and stronger. The trochanter has the interior margin more strongly curved and the stalk more distinct. The femur is very clumsy and scarcely twice as long as broad. The hand is comparatively broader and the fingers shorter than in the female.

Coxe (fig. 2 b). -The first three pairs of the coxa are shaped as in the female, but the fourth is very different. It is most narrow in the middle and enlarged towards both ends, slightly so inwards, but most distinctly outwards. The posterior side is distinctly concave, the anterior moderately convex, with a low median concavity. Near the interior posterior corner the entrance-opening (fig. 2b,c) of the coxal sac is seen. This sac (comp. p. 13 5 ) is almost as long as the coxa, which it almost fills, and is enlarged distally; the inner wall is provided with many subconical elevations or tubercles, each bearing one or several hairs, which most often are bifurcated from the base or middle, but sometimes divided into several branches. Near the opening these eminences are arranged in a kind of half-funnel.

Colour.--The colour is perhaps more bright, especially the purple of the anterior portion of body.

Measurements.-Cephalothorax $1 \cdot 1(0 \times 2-1 \cdot 68)$; abdomen 2.24 (2.52) mm.

Palps: trochanter 0.81』 (0.060); femur 151. (0.800);
tibia $1 \cdot 4(0 . \%)$; hand $1 \cdot 12(0.7 \% 5)$, height 0.730 ; finger 0.870 mm .

Young animal.-I have not had any opportunity of examining young animals, but only cast skins. The abdominal tergites of these had neither raised bands nor depressed areas. The fourth pair of coxæ is neither similar to those of female nor male.

Locality, Material.-I have examined five females and two males, besides a number of silk-cocoons containing animals in process of moulting or cast skins. They were all taken in Natal from the interior of bee-hives.

Remarks.-This animal, in spite of some peculiarities, is most naturally referred to a group of species which are nearly related to Ch. cancroides, L. The following characters of the males are common to these species:-lateral tergal keels, shape of genital area with ram's-horn-shaped organs, shape of fourth coxre with coxal sac, and bifurcated terminal tarsal hair. It is remarkable for the shape and granulations of body and palps, the broad coxæ of the female, and the shape of the posterior genital plate of the male.

Ecdysis.-Besides the animals which have been described, I have examined seven slightly curved circular silk-cocoons, which were sometimes placed two together. As they all contained animals in course of moulting, or cast skins, we must conclude that their purpose is to protect the animal during the dangerous process of ecdysis. These nidi show on microscopic examiuation a surprising structure, for the different threads are not independent and free, but are more or less fused, so that a complicated system or meshwork of thinner and thicker threads is formed (Pl. VIII. fig. 2 h ). The deusity of the meshwork varies considerably in the different cocoons, and is not the same everywhere in each cocoon. The area between the threads is sometimes many times, sometimes searcely broader than the threads. This structure is difficult to explain ; the newly-formed threads have perhaps fused before drying.

I found only a single cast skin (palps and legs not attached) in a cocoon without any animal. This skin was closed, with the execption of a very wide aperture in front; this opening was formed by the bursting of the membrane between the head and first tergite dorsally, and antenne and maxillie ventrally. The articular membrane is strougly dilated just behind this opening. The tergites are separated from the cephalothorax by a deep groove, and so strongly curved (downwards) that the last abdominal tergites almost reach and cover the coxa. The sternites are placed so closely to
the tergites that no room is left between; they are very difficult to distinguish from each other. The concavity of the sternites is consistently equal to the convexity of the tergites. The last two pairs of coxe are, on account of the curvature, covered by the first two pairs, and not visible unless the whole animal be stretched out. The antenne are without any comection whatever with the head, and fastened to the hindmost part of the maxillæ by a thin membranc. Other specimens were examined, which were killed during the moult. One, for instance, had the whole cephalothoras, front portion of abdomen, and femur of the palps frec. The cast skin of the cephalothorax was placed as a cap on the top of its abdomen.

## Chelifer equester, sp. n. (PJ. VIII. figs. $3 a-d$, Pl. IX. figs. $1 a-f$.)

8. Cephalothorax.-Two indistinct white ocular spots present. The cephalothoras, which is as broad bchind as it is long, has the sides slightly curved outwards; in front they approach each other, so that the front is much shorter than the hinder margin. There are no transverse grooves, but the head is nevertheless very well marked off from the thorax by being darker and more raised. The skin is minutely dotted, and bears a few moderately slender and clavate hairs in front as well as along the hinder margin of the thorax.

Abdomen.-The abdomen is distinctly longer than broad, and its dorsal sclerites are of almost equal breadth, but the first three are much shorter than the following, which increase slightly in length towards the tenth tergite. The hinder margin of the sclerites of at least the first two tergites is raised. All the tergites from the fourth (third) to the tenth are divided by a longitudinal line, which is rather imperfect in the middle of each sclerite. The granulation is indistinct; each sclerite possesses a hinder row of twelve loug, slender, and dentate hairs, each placed in the middle of a yellow spot; laterally at least one pair of hairs in front of the row on the hindmost segments; the hairs of eleventh tergite placed without order. Tenth and eleventh tergites with two pairs of exceedingly long and pointed "tactile" hairs. The fourth to the eleventh sternites are similar to the tergites, and, like them, longitudinally divided; but the fourth is much narrower than the others; the twenty-four hairs of each sternite, which are placed in transverse rows, are moderately slender and almost simple; the eleventh sternite bears at least three pairs of tactile hatirs in addition
to the usual hairs, arranged without order. Besides, the eleventh sternite possesses a great many (about 200) round spots, each with a median fissure, much smaller than the usual "lyriform" fissures; the corresponding tergite bears a smaller number, and the tenth sternite about 70.

The genital area (Pl. VIII. fig. $3 d$ ) is similar to that of Chelifer birmanicus, Thor., with a short backwardly curved third (?) sternite, and a long and broad anterior plate, between which is the opening; under the front plate several internal chitinous organs are seen.

Antennce (fig. $3 c$ ).-The flagellum probably consists of four hairs, like that of the female. The immovable finger bears three low blunt teeth just behind the tip, and thereafter five larger, decreasing in size backwards. The lamina exterior is well marked, and so is the lamina interior, the serruliform portion of which consists of six dentated lobes; the terminal spine bears many tecth internally. The short galea is provided with a few teeth (Pl. VIII. fig. $3 c$ ) : the scrrula exterior (fig. $3 c$ ) is very long and consists of 37 tecth, which are almost completely fused; the basal tooth is a good deal longer, enlarged distally, and provided with a membranous plate.

Maxilla.-The pointed distal portion of the maxillie is well marked and provided with a broad lamina.

Palps (Pl. IX. figs. $1 a-d$ ).-The palps are everywhere, with the exception of the stalks and partly of the fingers, provided with low granules; short and sleuder, but not quite simple, hairs are abundant; the tibia bears on the outer side near the base a pair of longer pointed hairs, and the fingers some tactile hairs. The trochanter, which is somewhat longer than broad, is provided with a distinct stalk. The inner margin is strongly convex ; the outer surface possesses a high tubercle; the upper a similar one near exterior margin ; there is a deep cleft between them. The upper tubercle (figs. $1 a-b$ ), which is directed upwards and slightly outwards, is triangular and as high as trochanter is loug, if measured from lower margin of segment to its top. The outer and lower tubercle is shorter, and its broad triangular base merges into a rather slender but blunt terminal projection (fig. 1 a). The femur, which is twice as long and somewhat higher than broad, is wider than the trochanter and provided with a distinct stalk; the latter merges gradually mo the moderate convexity of the inner margin, which is followed by a slight concavity ; the outer surface is regularly convex from the base to the tip. The upper side is much more suddenly and strongly convex than the outer,
while the lower surface is only slightly curved. The tibia (fig. $1 c$ ) is as long as, but broader than, the femur, with a very long stalk. The inner side has first a very deep notch to mark off the stalk, and is then irregularly and strongly convex ; near the tip there is a low concavity. The outer side is almost straight from the base to the middle, because both the basal projection and the eleration beyond it, which bears a rather long pointed hair (fig. la), are low as well as the concavity between; from the middle to the tip the outline is distinctly convex. In lateral view both outlines are regularly convex, almost semicircular. The hand, which is as long as the tibia, but broader, is higher than broad, 1.6 times longer than broad, and $1 \cdot 5$ times longer than the fingers. It is moderately convex inwards, and strongly so outwards, as well as above and below.

Core.-The coxæ are very similar to those of C. australiensis (fig. 2a), but those of the second pair are broader than those of the third more triangular pair ; the fourth pair (fig. $3 d$ ) are broader, with the hinder margin, which is longer than the inner, slightly convex on the middle.

Legs (figs. $1 e-f$ ).-The legs are rather short and clumsy. Their hairs are long, stiff, pointed, and almost simple. Near the base of claws a pair of simple strongly curved hairs, and near the base of the tarsus of fourth legs the usual interior and dorsal "tactile" hair. The long areola is shorter than the long claws. Both the tibia and tarsus of the first legs widened out distally, the former being much the longer' ; the tarsus of the fourth leg is comparatively much shorter than that of first pair, and scarcely longer than its femur is high.

Colour.-The palps and head have the surface polished, and are dark brown in colour, sometimes almost blackish, sometimes rather reddish; the maxille and the thoracic tergites are light reddish brown, with the posterior margin of the second tergite black. The abdominal tergites of a dull blackish-brown colour with white longitudimal line; the sternites are more yellowish brown, and so are the coxae and legs, but lighter.

Measurements.-Cephalothoras 1.75 (1.\%5) ; abdomen $3.75(2 \cdot 5) \mathrm{mm}$.

Palps: trochanter 1.26(0.98); femur 2.38 (1.221), height $\mathrm{I} \cdot 10$; tibia $2 \cdot 42(1 \cdot 316)$; hand $2 \cdot 38(1 \cdot 42)$, height $1 \cdot 54$; fingers 1.596 mm .

Leg i.: femur 1.56 ( $0 \cdot 448$ ); trochantin 0.728 ( 0560 ); tiljia $1 \cdot 232(0.308) ;$ tarsus 0.898 mm .

Leg iv. : femur $2.0(0.819)$; trochantin 0.712 ; tibia 1.590 $(0.42)$; tarsus 1.064 mm .

ㅇ. Abdomen.-The genital area, which is covered by the fourth pair of coxæ, differs from that of the male.

Antenne (Pl. VIII. figs. $3 a-c$ ). The flagellum (fig. $3 a$ ) is composed of four hairs, of which the three posterior are simple and decreasing backwards, while the anterior is bifureated and very much widencd out in the middle, where about five larger and smaller pointed teeth are found. The scrruliform part of lamina interior with five dentated lobs (fig. $3 b, s$ ). The moderately long galea (fig. $3 c$ q) possesses about three rather long terminal branches, as well as some few distal, short, blunt teeth. The serrula exterior is composed of about 40 teeth.

Palps (Pl. IX. figs. I $a-d$ ).-The palps are much shorter than those of the males. The inner margin of the trochanter is gradually curved (fig. 1b) ; the posterior and superior tubercles are comparatively lower than in the male. The posterior and inferior tuberele is rather low and blunt, while the superior is high and, in bearing a tooth-like projection, resembles the lower of the two prominences in the male. The femur, which is more than twice as long as broad, has the inferior and superior outlines much less convex than in the male. The upper and lower convexities of the tibia (fig. $1 c$ ) more even than in the malc. The hand is much broader than the tibia ( 1.35 ) and 1.4 times longer than broad.

Coxe (Pl. VIII. fig. $3 d$ ) .-The fourth pair is scarcely widened out distally and has the inner margin as long as the hinder.

Colour.-The colour is much lighter, especially on the palps, which are light reddish; the head is scarcely darker than the thorax. The ventral surface, including the maxillit, is yellowish brown. There is great difference between the specimens, as the darkest amongst them are scarcely lighter than the males.

Measurements.-Cephalothorax $2.0(2 \cdot 0)$; abdomen 3.0 $(2 \cdot 5) \mathrm{mm}$.

Palps: trochanter $1 \cdot 12(0.728)$; femur $1 \cdot 96(0.84)$; tibia $1.932(0.952)$; hand $1.876(1.316)$, height $1 \cdot 46$; fingers 1.35 mm .

Leg i.: femur $1.4(0.42)$, trochantin $0.616(0.504)$; tibia $1.134(0.308)$; tarsus 0.84 mm .

Leg iv.: femur $1.976(0.817)$, trochantin 0.74 ; tibia 1.540 ( 0.364 ) ; tarsus 1.064 mm .

Material.-Mr. F. J. Jackson collected 8 ㅇ and 13 ठ bencath the elytron of a beetle at Taveita, Kilimanjaro.

Remarks.-This species, which seems to be related to Ch. javanus, 'Thor., is especially remarkable for the prom nounced sexual difference in the structure of the palps. In spite of these differences, I have referred the males and the females to the same species on account of the great number in which they ocenr together, and the similarity in the rest of their structure.

> Ideoroncus mexicanus, Bks. (Pl. IX. figs. $2 a-d$, Pl. X. figs. $1(a-f$.
1898. N. Banks, (14) p. 289.

Cephalothorax (fig. 2a).-Two well-developed eyes, placed at the lateral margin, and as far removed from the front margin as length of their diameter. The ecphalothoras, which is distinctly longer than broad posteriorly, has paraltel sides and is of almost equal breadth behind the eyes, but much narrower in front of them. Anterior margin is marked off from posterior part of head by a line; it is prolonged into a blunt "epistoma" and bordered with a thin membrane. The skin is smooth and provided with moderately long, pointed, simple hairs.

Abdomen.-The abdomen is distinctly longer than broad in the middle, where it is broadest, very narrow anteriorly, and thereafter almost oval with regularly curved sides. The tergal sclerites are in this specimen, which is dilated with eggs, much shorter than the thinly chitinized membranes between. The sclerites, especially of the anterior and posterior tergites, are indistinctly marked off, and the hindmost row of hairs is placed behind their posterior margin. There is a shallow longitudinal depression through the middle of each sclerite; the tergites seem to be smooth. Each tergite bears about four pairs of hairs, which are longer on the posterior tergites than on the anterior ones; the tenth and cleventh tergites each bear, in addition to these, two pairs of "tactile" hairs.

The sternites are scarcely different from the tergites, with the exception of the third and fourth, which are very narrow, indistinct, and divided in the middle.

The sides have well-marked grooves between the segments and possess densely placed, narrow, parallel and longitudinal ridges.

Antenne (Pl. IX. figs. 2b-l $l$ ). -The fingers gape slightly when closed (fig. 2d). The flugellum is composed of three short hairs, which are placed rather apart from each other and provided with some few tiny spines (fig. :2 (b). The tij)
of immorable finger long, slender, and moderately curved; behind the tip, and well removed from it, is situated a strong, conical, dorsal, marginal tooth, followed by about five more or less distinct low and rounded teeth (fig. $2 d$ ).

Serrula interior (fig. 2b) consists of eighteen tecth, of which the proximal are more or less squarely truncate and almost completely fused-four basal ones excepted, - while the distal are much more free, pointed, and minutely spined along posterior margin. No independent terminal spine placed on a lower level than the teeth of the serrula proper is present, as is the case in Ideobisium Balzanii and crassimamm, Bal. (comp. Hansen, 15, pl. v. fig. $6 b$ ), as well as in two undescribed Indian species examined by me-unless the last tooth of the serrula should correspond to it.

The galea (fig. $2 c$ ) is slender, moderately long, curved, and blunt; a few minute teeth are noticed near the tip. The terminal point of the movable finger is distinctly longer and more curved than that of the other finger; above its terminal hook we find a much shorter and stouter one. The tip of the immovable finger is placed between these two when the hand is closed. Behind the described dorsal tooth a long and broad marginal projection is placed, which on the right antenna has the margin slightly folded (fig. $2 d$ ), and on the left (fig. 2c) is broken up into blunt teeth.

The serrula exterior, of which a distal third portion is frce, consists of about twenty teeth, which are squarely truncate and touching each other in almost their whole length (fig. 2c).

Maxille (Pl. X. fig. $1 a$ ). -The labrum is well developed and widened out distally. The median triangular portion of the maxille, seen from below, appears strongly raised and falls stecply laterally. In front we find, as usual, an interior marginal lyriform organ, cousisting of a single semicircular fissure (fig. la,i), and more behind a median lateral one, consisting of several more or less curved fissures (fig. $1 a, m)$. The terminal portion is thinly chitinized, placed on a higher level than the basal region, and is provided with two pointed hairs; at its base a single very long and slender one is situated. Along the terminal portion a narrow lamina inferior (?) is placed, and in addition to this a broader and longer lamina superior.

Pulps (Pl. X. figs. Ib-c).-The palps seem to be smooth, with the exception of the exterior basal elevation of the fomur, which is gramular. Longer or shorter, pointed and simple hairs are abundant everywhere. The hand bears
besides a single tactile hair near the inner margin and nearer to the middle than to the base (fig. $1 b, 1$ ); the immovable finger possesses on the outer surface three tactile hairs near the base and two more distally (fig. $1 c, 4-8$ ) ; the dorsal surface with two distal hairs (fig. 1 $b-c, 2-3$ ), and the immer without any. The movable finger has four tactile hairs on the outer surface (fig. $1 c$ ). Outside, near the base of the fingers, we find a peculiar organ, shaped like a compressed horseshoe (fig. l $c, h$ ) and with a clear spot inside. Four similar ones are found interiorly near the upper margin at the base of the finger, the one placed above the other, each consisting of a low elevation with almost oval outline, and provided with a round clear spot at the top in the middle; each of the spots seems to possess a median dot (comp. 15, p. 201).

The trochanter, which is twice as long as broad, is distinctly stalked and gradually widened out distally; the inner side is, with the exception of a low basal concavity, regularly convex from the base to the tip; the outer side is slightly curved inwards. The femur, which is 3.0 times longer than broad, is provided with a distinct but short stalk; theinterior side is slightly and almost regularly convex from the base to the tip; the outer side has, after the shallow wotch which marks off the stalk, a low elevation ; beyond this there is first a low concavity and then a moderate convexity. The tibia, which is slightly shorter and broader than the femur, is distinctly stalked and gradually enlarged distally; the inner side, beyond the concarity which marks off the stalk and the following low elevation, is slightly convex or, more correctly, shaped as a very open obtuse angle; the outer side is almost straight both before aud bevond the scarcely visible elevation of the stalk and at last slightly convex. The hund, which is a little shorter than the tibia, but nearly twice as broad as the femur, is higher than broad and shorter than the finger. The convexities of the superior and especially of the interior surfaces are much more marked than those of the inferior and exterior ones. Both fingers bear obtuse, squarely truncate, densely placed teeth; the tip of the immovable finger is much more hooked than that of the movable one.

Coxa (PI. X. fig. $1 a$ ). -The coxe are all placed on the same level, but on a lower level than the maxille. The first pair is almost as broad as long and scarcely cularged towards the extremities; the second pair is of almost equal breadth, but distinctly enlarged distally ; the third pair is so much enlarged distally that it becomes almost triangular, but much less marked than the curresponding pair in

Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.

Ideolisium Balzanii. The fourth pair is broader again, enlarged distally, with the posterior corner smoothly rounded like the postero-exterior, which is produced backwards.

Leys (Pl. X. figs. $1 d-f$ ).-The skin of the legs, especially that of the femora and tibire, seems to be minutely shagreened; we find more or less long, pointed, and simple hairs everywhere. An exceedingly long "tactile" hair is placed dorsally near the base of first tarsus of the last two pairs of legs. On each side near the base of the claws is placed a rather short hair with some few teeth distally along its upper margin (fig. lf). The areola is shorter than the slender claws. The legs are long and slender. The basal femoral part of the first pair of legs (fig. 1 d) is three times as long as high and twice as long as the distal part. The tibia is slightly shorter than the basal femoral part and a little longer than the second tarsus, which is about 25 times longer than the first. The femur of the fourth pair (fig. ] $\epsilon$ ) is rather slender and three times longer than high; the articular membrane of the rather short trochantin is not straight as usual in Ideobisium (cf. p. 134), but oblique as in Olpium. The tibia is distinctly longer than tarsus ii., which is more than twice as long as tarsus i., but shorter than both tarsi together. The trochanter of the first pair of legs is enlarged distally and only a little longer than high; that of the fourth pair is much more slender and almost twice longer than high.

Coluur.-The palps and maxillæ are yellowish brown with darker fingers; the cephalothorax is brown; the abdominal tergites are lighter with yellowish interarticular membrane : white spots, placed under the skin, are seen everywhere. The coxæ are brownish and the legs yellowish, both with a greenish shade.

Measurements.-Cephalothorax 0.720 ( 0.588 ) ; abdomen $1.820(1.036) \mathrm{mm}$.

Palps: trochanter $0.392(0.196)$; femur $0.784(0.214)$; tibia $0.728(0.245)$; hand $0.700(0.388)$, height $0 \cdot 420$; finger 0.800 mm .

Leg i.: femur i. $0.396(0 \cdot 105)$; femur ii. $0.198(0 \cdot 100)$; tibia $0.315(0.081)$; tarsus i. $0 \cdot 125$, tarsus ii. 0.305 mm .

Leg iv.: femur $0.675(0225)$, trochantin 0.235 ; tibia $0.495(0 \cdot 108)$; tarsus i. $0 \cdot 162$, tarsus ii. 0.360 mm .

Material.-Mr. II. II. Smith collected a single female near Chandilly (Windward Islands) at a height of 800 fect, March 14th, in fermenting cocoa-husks (shady place).

Remarks.-I have referred the above-described species to

1d. mexicanus, Bks.: the minor points in which this species differs from Banks's description seem not to be sufficient for establishing a new species; but, on the other hand, we must admit that the description mentioned is too insufficient and lacking in important details for settling the question definitely.

The differences are the following:-The cephalothorax is only $1 \cdot 2$, not $l \cdot 5$, longer than broad; the trochanter of the palps can scarcely be called swollen behind; the tibia is almost as long as the femur, not one fourth shorter; the tibia can scarcely be called "short pedicellate" and is slightly broader than femur, not merely as broad.

This species is most easily distinguished from Ideoroncus pallidus, Balz. (io, p. 444), as well as from two undescribed species from Siam, which I have examined, by the flagellum, which consists of three short hairs, but especially by the tactile hairs of the hand; Id. mexicanus bears only a single dorsal one, while the others bear four, placed in a trapezoid. On account of its slender palps and the arrangement of tactile hairs, it presents no similarity to Id. gracilis, Balz. (ı1, p. 540). From Id. obscurus, Bks. (12, p. 66), it differs by the simple undivided galea, by the palps, which are longer than the body, femur of the palps longer than the cephalothorax, and fingers distinctly longer than haud.

Ideobisium Balzanii, sp. n. (Pl. X. figs. $2 a-h$.)
ठ. Cephalothorax (fig. 2a).-The comparatively large eyes are placed near to each other at the lateral margin, removed from the front margin a distance about as long as their diameter (fig. 2a). The cephalothorax, which is a little longer than broad posteriorly, has almost parallel sides, and is of nearly equal breadth behind the eyes, but slightly narrower in front of them. The front margin passes into a rather broad, rounded, median "epistoma." There are no transverse grooves. The skin seems to be smooth, and is provided with moderately long, slender, and pointed hairs everywhere.

Abdomen.-The abdomen is distinctly longer than broad and broadest in the middle. The sclerites of the tergites are, with the exception of the eleventh, of almost equal breadth and length (the second and third are a little shorter), and well separated from each other by long thin-skinned membranes. The sclerites seem to be smooth and bear some few simple pointed hairs along the hinder margin; those in the middle are rather short, but the more lateral
ones are long and slender. The tenth and eleventh tergites bear a pair of "tactile" hairs each. The sides of the alodomen are minutely shagreened. The fifth to the eleventh sternal sclerites are similar to the tergal, but they are rather short in the middle and widened out laterally; the hairs, which are long and slender, are not placed along the hinder margin, but behind. The sclerite of the fourth sternite is divided into two well-separated triangular portions. The sclerite of the third sternite is better marked and provided with short hairs along hindmost margin and with the front margin curved inwards in the middle. In front of this stemite, which constitutes the hindmost genital plate, and between the fourth pair of coxer, a complicated system of immer organs belonging to the male system are visible.

Antenue (figs. 2a-b).-The antemme are large and gape distinctly when closed. The flagellum consists of at least six long sleuder hairs, provided with densely placed tiny teeth along the front margin ; the hindmost hair is considerably shorter than the others. This flagellum presents great similarity to that of I. crassimanum, Balz. (cf. H. J. Hansen's figure, 15 , tab. v. fig. $6 f$ ). The immovable finger possesses along its inner margin a dorsal row of many tiny teeth, which vary in number and size in the different specimens.

The serrula interior is very similar to that described by Hansen in 1d. crassimanum, Bal. (fig. 6 b); the basal teeth are placed near to each other and are very short compared with the distal ones, which are almost completely free, slightly curved, pointed, and with the hinder margin serrated; this serrula seems to be fused with the finger in its whole length to base of terminal tooth. Independent of this serrula, and placed on a lower level, there is a very long, slender, and curved spine, slightly dentated along its hinder margin; we find a similar one in I. crassimanum, but less curved.

The galea is rather long, slender, and blunt; its root is well removed from the tip of the finger. The end of the movable finger is moderately curved (fig. 2a); behind the tip the dorsal margin possesses six to ten teeth, which are of unequal size in the different specimens, and even in the two antemme of the same specimen.

The serrula exterior is very similar to that drawn by Hansen for I. crassimanum (fig. 7); its distal portion is free; there are about 30 teeth, which are larger distally and are more or less fused. When the serrula is observed
from the edge (fig. $2 b, s$ ), it will be seen that the proximal portion is directed more downwards, the distal more upwards. If we examine the antenne in their natural position, we will see the immovable from the edge with the serma interior directed downwards and outwards, working against the serrula exterior (fig. $2 a$ ).

Maxille (fig. 2c).-The maxillæ, the hindmost portion of which is covered by the first pair of coxa, appear more trapezoid than triaugular; the terminal portion is moderately pointed, only this bears a long slender hair at the base and several shorter ones distally ; a distinct long lamina maxillaris is present.

Palps (figs. 2d-e). -The palps seem to be smooth with the exception of the inner surface of the hand. More or less long and slender hairs are found everywhere; those of the inner side are the longer; the inner surface of the hand bears two very long hairs; the hairs of the fingers are placed more densely. The hand bears exteriorly three tactile hairs (fig. 2e,6-8), one more forwards and two a little more backwards, the one above the other. The immovable finger possesses on the outer surface two tactile hairs (figs. 2e, 4-5), and on the dorsal surface three (fig. 2d, 1-3). The movable finger has one tactile hair at the base and three, one above the other, in the middle (fig. $2 e$ ).

The trochanter is distinctly stalked and longer than broad; the inner side is marked off from the stalk by a moderate convexity, and is beyond almost straight to the end; the outer side is extremely short and concave. The femur, which is $2 \cdot 5$ times longer than broad, has a very short stalk; the inner surface has first a moderate convexity and thereafter a slightly pronounced concavity ; the exterior side is first provided with a short and low elevation just beyond the stalk, and is then almost straight. The tibia, which is slightly shorter and broader than the femur, is distinctly and shortly stalked; the inner outline is almost semicircular beyond the deep notch which marks off the stalk ; the exterior side is proximally almost straight, but for a very low elevation near the base, and distally very strongly convex. The hand, which is as long as femur and 1.8 times broader, is almost 1.5 times longer than broad and as high as broad ; it is only a triffe longer than fingers, which are distinctly longer than the hand is broad. Both interior and exterior surfaces are much more strongly convex than the superior and inferior. The marginal teeth of the fingers are placed near to each other and squarely truncated.

Coxa (fig. 2 c ).-The coxæ are not placed completely on the same level; the first pair covers the hindmost portion of the maxille. The first pair is almost as broad as long; the second pair is a little longer and slightly enlarged distally ; the third pair, the front margin of which is covered by the second, is widened out distally so considerably that its shape becomes almost triangular. The fourth is as broad as the third is distally and is almost trapezoid ; the posterointerior corner is obtuse, and the postero-exterior is rounded but scarcely produced backwards as in Ideoroncus mexicanus, Bks. (Pl. X. fig. 1 a).

Leys (figs. $2 f-h$ ). -The skin of the legs seems to be smooth. We find more or less long, pointed, and simple hairs everywhere; a dorsal "tactile" one is placed near the base of the first tarsus of the fourth pair of legs. A long pointed hair, which is provided with many teeth, especially downwards, on each side near base of the claws (fig. $2 h$ ). The claws are strongly curred and longer than the areola. The legs are less long and slender than in I. mexicanus; the basal femoral part of the first pair of legs (fig. lf) is three times longer than high and 1.4 as long as the distal part. The tibia is as long as the basal femoral part, distinctly longer than the second tarsus, and only a little shorter than the two tarsi together ; the distal portion of the tarsi is twice as long as the basal. The femur of the fourth pair (fig. 2g) is about twice as high as long ; the trochantin is almost half as long as the whole femur, with straight articular membrane. The tibia is a little longer than the two tarsi, of which the distal is almost twice as long as the basal.

Colour:-The hand and the tibia of the palps are reddish brown; the basal joints, maxille, and coxæe are darker or paler yellowish brown; the legs are very pale. The cephalothorax is brownish; the abdominal sclerites are lighter and more brilliant. Some of the specimens are paler, while others are darker.

Measurements. - Comparatively small specimen from St. Vincent. Cephalothorax $0.513(0.450)$; abdomen 0.990 $(0.540) \mathrm{mm}$.

Palps: trochanter $0 \cdot 224(0 \cdot 144)$; femur $0 \cdot 425(0 \cdot 162)$; tibia $0.378(0.207)$; hand $0.410(0.288)$, height 0.288 ; finger 0.360 mm .

Leg i.: femur i. $0.207(0.099)$; femur ii. $0 \cdot 152(0.099)$; tibia $0.207(0.0(3)$; tarsus i. 0.090 ; tarsus ii. 0.170 mm .

Leg iv.: femur $0.468(0.207)$; trochantin $0 \cdot 225$; tibia $0.360(0.095)$; tarsus i. 0.126 ; tarsus ii. 0.225 mm .
9.-A much darker specimen from Upper Richmond Valley is probably a female; as the following dimensions make evident, neither the absolute nor the relative proportions are quite alike; but in all other respects it seems to be similar to the above-described male, which is perhaps a young one.

Cephalothorax 0588 (0532) ; abdomen 1•260 (0.700) mm.
Palps: trochantin $0 \cdot 280(0 \cdot 168)$; femur $0 \cdot 06 t(0 \cdot 210)$; tibia $0.476(0.252)$; haud $0.560(0.392)$; finger 0.448 mm .

Material, \&c.-This species seems to be very common in the West Indies. I have examined specimens from several localities at St. Vincent, collected partly by Mons. E. Simon and partly by Mr. H. H. Smith; the latter seems to have taken most of his specimens under rubbish or rotten leaves in mountainous forests (1200-3000 feet) during the months from January to March.

Remarks.-This species seems to be nearly related to Id. crassimanum, Bal. ( 1 , p. 542 ), from which it differs in the following characters:-The abdominal sclerites seem to be smooth, not granular; the epistoma is rounded, not subconical ; the immorable finger of the palp has three, not two, tactile hairs; the hand is not 1.7 times longer and not 1.3 times broader than fingers are long, but longer than hand is broad.

## II.-Coxal Sac. (Pl. VII. fig. $4 b-f$.)

If we carefully examine the fourth pair of coxæ in the male of Chelifer socotrensis, sp. n., we shall find a remarkable organ which I propose to call the coxal sac. This organ is only slightly developed in this species compared with many others more or less nearly related to Ch. cancroides, L., for instance, Ch. sculpturatus, Lewis (p. 121); in this paper I shall give only the description of its structure in Ch. socotrensis. My investigations on its modlifications and fuller development in other forms I hope to get finished in a not too distant futurc. The cosal sac is situated in the inner and hinder part of the cosæe, and directed towards the posteruinterior corner (Pl. VIJ. fig. 4b), where probably an opening is found through which the hairs of the funucl are directed. The sac, which is rounded and elongated, consists of two portions which are well marked off from each other dorsally and laterally. I was not able to settle the question whether the sides which I have called dorsal and ventral really are so or not. I use these terms because the position of this organ in one of the specimens I examined seems to
bear out this opinion. The two parts into which the cosal sac is divided are of very unequal size; the basal, which is nearest to the postero-interior corner, is only half as spacious as the distal part. The two portions are dorsally and laterally separated from each other by a rather deep groove as well as a chitinous ring (figs. $4 e-f$ ), but ventrally there is no such distinction (fiys. $4, c-c$ ). Not only the outer surfaces, but also the inner cavities, are well marked off from each other except ventrally. Just between the two portions, and, as it seems, fastened to the above-mentioned ring, we find a "fumel" of hairs, which is open below (figs. $4 e-f, b-f$ ). There is consequently no direct communication between the two cavitics except ventrally. The units which build up the fumel are of two kinds; its wider basal portion is more solid and secms to have been formed by the fusing of elongated tubercles like those with which the inuer walls of the distal sac are beset. These tubercles are not in every case all fastened behind to the abore-mentioned ring, becatse at least some are seen to be free posteriorly and project into the distal cavity (fig. te). The more narrow distal part of this funnel is composed of a number of long, slender, and pointed hairs which converge towards each other and are directed through the round entrance-openir. $g(o)$ of the sac $(t)$. This entrance opening, which is found just at the end of the organ, is, at least in other specics, connected with an opening in the rentral wall of the coxæ, and the abovementioned hairs project through this opening. The dorsal aud partly the lateral walls of the distal cavities are provided with subconical tubercles which project into the lumen (figs. $4 e-f, h$ ); each tulercle bears at least one terminal pointed hair. These tubercles are sometimes supported by chitinous ridges. The skin of the cosal sac is everywhere minutely grauular.

## III.-Abnormal Segmentation.

## Chelifer sculpturatus, Lewis. (Pl. VIII. fig. 2a.)

One of the dried $f$ males of this species which I examined showed some abnormalities in the segmentation. The first abdominal tergite is normal (Pl. VIll. fig. 2a) ; all the following are, as usual, divided into a right and a left portion by a longitudinal line. The left portions of the second and third tergites are well separated laterally, but fused in the middle, because the groove between them has been gradually abolished. The depressed areas and the ridges between show
also some irregularitics. The other half part (the right) of the second tergite is rather short, but otherwise of usual shape; it is separated in its whole length from the right portion of the third segment, which is distinctly widened out towards the middle. If we regard the two segments as a whole, it will easily be seen by looking at the figure that the two half parts are of almost equal length laterally, but that the right half is distinctly longer than the left in the middle. The longitudinal line between the two is not parallel to the longitudinal axis of the body, but forms an acute angle with it. The left portion of the fourth tergite is rather long and well separated from both the third and fifth, especially towards the middle, where it becomes narrower. The right half is exceedingly narrow and rather short; the space between the two portions is very well marked, being twice as broad as the right half and more than half as broad as the left half. The wide open area thus formed is limited behind by the convex margin of the right half of the otherwise regular fourth tergite ; it is like an attempt at lesseuing the unprotected wide space. The rentral side shows no trace of these irregularities.

## Chelifer javanus, Thor., ठ๋• (Pl. VIII. fig. I a.)

As I looked over the collections of Chelonethi from Iudia I discorered a specimen ( $\begin{gathered}\text { from Tharravadi, Burma) which was }\end{gathered}$ remarkable for its abnormal segmentation. The first and second abdominal tergites are normal, but the two following show a peculiar structure. The left half of the third tergite is fused with the right half of the fourth. I have not been able to distinguish the longitudinal line which elsewhere divides the sclerites, and it is consequently impossible to tell where the one begins and the other ends. The right half of the sclerite thus formed is much longer and somewhat narrower than the left. The right half of the third tergite is without comexion with the corresponding left half; its sclerite is triangular and rather short. The left portion of the fourth tergite passes into the right, but its sclerite has no commexion with the selerite of the right side. The positions of the hairs are as usual, and, as seen in the figure, not the same in the third and the fourth tergites. The right side of the latter shows some irregularities, as the hindmost row of hairs are placed behind the hinder margin of the selerite. The ventral side shows no trace of the described abnormalities.

In the following I enumerate a few similar cases of
abnormal segmentation found in Arachnids, Insects, and Annelids :-

Arachnids.-In Hansen and Sörensen's paper (24, p. 97, pl.ii. fig. 2 a) I came across a figure of Stylocellus sumatranus, Westw., one of the Cyphophthalmi, which shows that the groove between the fifth and the sixth tergite on the left side is incomplete; a kind of split segment is thus formed. If the right half of the sixth tergite is fused with and undistinguishable from the right part of the fifth the abnormality is of another nature than that found in Ch. javanus; but if it is connected with the right half of the seventh tergite the similarity to the above-described case is unmistakable.

Insects.-In the collections of the British Museum I found some specimens of Hymenoptera showing abnormalities in the segmentation. By the kind assistance of Col. Bingham I am able to give the names of the insects in question. In Trans. Ent. Soc. (23) I found a short note about one of these animals by the Rev. F. D. Morice, who had collected the specimens. He exhibited to the Society a specimen of "Gorytes quinquecinctus (fossor) with the abdominal segments twisted out of their proper shape and place." The animal so named is, according to Col. Bingham, not a Gorytes, but Cerceris quinquefasciata. The cases are the following :-

1. Polistes sp.-The first and the second segments are normal, the latter being provided with the usual yellow spots and marginal band, but the two following tergites are irregular. The left side of the third passes without any limitation whatever into the right side of the fourth, and so does the yellow band along the hindmost margin, which is directed obliquely backwards. The right portion of the third tergite, which is bordered with yellow, is well separated from the left and is short and narrow. The left portion of the fourth is even less marked, almost triangular, bordered with yellow, and without communication with its right part or with the filth tergite. The latter is almost normal if the irregularly shaped anterior and posterior margius be excepted. Ventrally and laterally the segmentation appears normal.
2. Megachile sp.-The dorsal side shows the following abnormalities :-'The hindmost margin of the third segment is not quite transverse, but slightly oblique, so that its right side becomes longer than its left. The left halves of the fourth and the fifth segments, which are well separated by a
groove bordered with thin yellow hairs, are both fused with the right half of the fourth tergite, which is rather short, especially laterally. The right half of the fifth tergite is consequently without connexion with its corresponding half ; it is short, almost triangular, and bears the usual marginal row of yellow hairs.
3. Cerceris quinquefasciata. - The segmentation shows dorsally very remarkable variation. The first segment is normal; the left half of the second tergite, which bears a moderately large yellow spot, merges into the right half of the third, being rather short and almost yellow, on account of its prominent spot. The right portion of the second segment, which is very small and with a tiny yellow spot, is well limited from the tergite thus established. The left half of the third tergite, which is almost yellow, is well separated by a groove from the left part of the fourth, but passes into its right half without any limitation. The fourth segment, together with the one half of the third, becomes thus a split segment ( $c f$. Morgan, 19, p. 245).

Many cases of a similar kind of abnormality or variation in the segmentation have been described in different forms of Annelids (compare the literature, 18-2I). In outer appearance many of these abnormalities (Cori, 18, Taf. xxv. figs. $5 a, b$ ) are very like those described here, especially in Megachile (segments iv. and v.) and Cerceris (segments iii. and iv.), and also in Chelifer javanus, Thor. (Pl. VIII. fig. 1 a). Cori ( $18, \mathrm{p} .576$ ) characterizes the abnormality in the following manner :-"Dass die äusseren Segmentgrenzen der betreffenden Körperabschnitte nicht die Form von Kreistouren haben, sondern Schraubenlinien beschreiben." It has also been called "spiral segmentation" (Bateson, 21).

Even if there is great similarity between the more simple cases of "spiral segmentation" in the Annelids and the abnormalities found in the segmentation of the abovedescribed Articulata, it remains to be proved that the similarity is more than superficial. The number of the segments is not so constant in the Annelids as in most Arthropods, and the individuality of each segment, especially in the inner structure, is more pronounced in the former than in the latter group. The distinction between dorsal, ventral, and lateral parts within each sternite is better marked in the Arthropods. All these are reasons to be careful in comparing and identifying similar phenomena of this kind in the two groups. Different authors have tried to explain the
spiral segmentation, but in different ways. In the Arthropods there are at least two modifications, viz.: "the split segment," in which the one half of a segment is fused with its fellow half as well as with that of another segment; and the modification in which the one half of one segment is fused with the opposite half of the following, without having any connexion with its own corresponding half. Both modifications are found in Cerceris and an intermediate link in ('helifer javanus (Pl. VIII. fig. $1 a$ ). The abnormality of Ch. sculpturatus (P]. VIII. fig. 2 a) seems to be somewhat different. Whether the abnormalities mentioned are due to injuries in the embryos or later on in life or to quite different causes caunot be decided until a larger number of forms, especially of Myriopods, have been examined.

## Literature.

Fiy. $2 \% \delta^{\circ}$. Inner lateral hair of left tarsus iv.

# BIBLIOGRAPHICAL NOTICES. 

Birds by Land and Sea. By John Maclar Boraston. London: Johu Lane, 1905.

"Hearexs! Another bird-book!" was the first exclamation which escaped us on unpacking this volume. But a glance at the beautiful illustrations which are copiously distributed throughout its pages soon convinced us that the book had at least one redeeming feature. Later, when we came to play the critic, we discovered that this was a work of real excellence, a perfectly charming series of essays, one for each month of the year.

The author seems to have written out of sheer love of his sulject, rather than with a view of writing a book which, perchance, might "sell." His enthusiasm is infectious!

Possessing an unusual facility of expression the author is able to make even the most everyday fact of his subject interesting. Keen insight and power of interpretation are everywhere apparent in these essays, while here and there he is able to show his less fortunate brother naturalists something of the mysteries of the inner life of birds which are but rarely to be encountered. His observations, for example, respecting the migration of the starlings and his notes on their "pairing flights" are new to us.

The author's comments on the evils unfortunately inflicted on our native avifauna by the game-preserver are peculiarly to the point and have our most cordial sympathy. Never has the case been stated more clearly or more forcibly. He also inflicts a well-merited castigation on a certain Field " Naturalists""(!) Club, whose conduct at Puffin Island ill-agreed with their title to the claim of " Naturalists."

Valuable hints on the methods of one of the most difficult branches of photography-the photography of living birds-are dropped incidentally by the author, and for these many who read this book will be grateful.

Books by what we may call camera-naturalists are legion, but this is one of the very best that has yet appeared.

W. P. Pycraft.

Our Country's Animals, and how to know them. By W. J. Gordon. London: Simpkin, Marshall, \& Co. (n. d.).

This volume is the last of the series which have appeared under the above title. We suppose it will be useful to some people, and, so far as we have examined it, it appears to be fairly accurate; but we would point out that the metapterygoid has nothing to do with the quadrate boue, the astragalus and calcancum are not metatarsal
bones, the Microchœridæ do not belong to the Insectivora but to the Lemurs; Hyracotherium was not Tapir-like, and Ornithostome was not a Crocodile.

We note, as in former volumes, too many instances of loose mriting, such as "The land Carnivores can be sorted out on their hind toes "
The long lists of names of fossil species serve to fill out the book, but it is doubtful whether they fulfil any other useful end whaterer.

## MISCELLANEOCS.

> The Echinoid Name Discoidea subucula. By F. A. Bather, Brit. Mrus. (Nat. Hist.).

A friendey criticism of the labels attached to specimens of this Cretaceous Echinoid in the Geological Department of the British Museum has caused me to look the matter up. There is nothing rery norel in the conclusions to which I have been led; indeed the tangle was almost entirely unravelled by Mr. J. Lambert twelve years ago *. But there are four reasons for reopening the question: first, Mr. Lambert's views appear to have passed unnoticed by British authors, in spite of the 'Zoological Record'; secondly, his conclusions are vitiated in the eyes of most zoologists by his acceptance of the pre-Linnean and unbinomiual writer Klein; thirdly, a further erroneous alteration of the nomenclature recently appeared in a book for which I was largely responsible; and, lastly, after lying perdu for just a century, another use of the name Discoides claims attention. It may therefore be well to defend the name at the head of this note.

The name Discoides was invented by Klein $\dagger$ for a genus of his section Fibula, he saying in explanation:-" Discoidem appellamus mutuato nomine a figura Disci veterum (ff) qui cum vase ligneo
"(ff) Lucerna pregrandis \&c. cœenarumque reliquiis discus $\mathbb{\&} c$., Apul. 2, Miles, p. 125. ."
tornato conrexo-concaro, quo nos reliquias ex mensa reponimus, comparari potest. Tischkorb, Tellerschussel." The sole species mentioned under this name tras called by him Discoides subuculus.

Sereral of Klein's names were legitimized in 1778 by Leske in

* "Recherches sur les Echinides de l'Aptien de Grandpré," Bull. Soc. Géol. France, (3) xx. p. 77 et sqq.; Nor. 1892. See further, Lambert, "Étude . . E Echinides crétacés dans l'Yonne," Bull. Soc. Sci. Yonne, xlviii. pp. 58, 50; 1894.
$\dagger$ Nat. Disp. Echinodermatum, p. 26 ; 1734. Amm. \& Mag. N. Hist. Ser. 7. Vol. xv.
his 'Additamenta ad. . . Klein \&e.'; but the name Discoides was not so endorsed. On the contrary, Leske threw Comulus and Discoides, Klein's two "genera" of Fibula, into a single geuus, for which he proposed the name Echinites*. The sixth species of this was Echinites subuculus Leske ex Klein.

The first writer to resuscitate Discoides appears to have been James Parkinson, who in vol. iii. of 'Organic Remains' (1811) gave a good account of fossil Echinoids, based upon, but not blindly following, that of Leske. On p. 20 he says, "The second genus of this section is Discoides, the only species of which is subuculus."

Parkinson has been strangely overlooked, and most writers have taken J. E. Gray $\dagger$ as the authority for the genus, and have supposed themselres to be following him in spelling the name "Discoidec." In Gray's paper, however, the spelling is "Discodea," which may be a misprint for Discoidea, or, as Mr. Alexander Agassiz has supposed, for Discoides, since anything is possible in a paper so full of misprints. As type, Gray quoted Galerites rotularis, Lamarcl's name for Discoides subuculus. The spelling Discoidea seems to have been first used in 1836 by L. Agassiz $\ddagger$, who, under the heading "Discoidea macropyga Agass." (p. 137), wrote:"M. Gray a judicieusement distingué de nouveau les Galérites à ambulacres étroits, que Klein désignait sous le nom de Comulus, et dont le G. vulgaris Lam. est le typo, de celles dont les aires ambulacraires sont sensiblement plus larges, et que Klein appelait Discoidea [sic], pour en faire un genre dont le G. rotularis Lam. est le type." In his systematic summary of slightly later date (p. 186), under "Les Clypéastres," he placed [Genus] " 4 . Discoidea Kl. et Gr. (Conulus Leske.-Echinodiscites V. Ph.-Galerites Lam.)"; then follows the diagnosis and list of species, including "D. rotularis Kl. [sic] (Galerites rotul. Lam.)." Therefore those who, for good or bad reason, prefer the form "Discoidea," should write "Discoidea Agassiz (emend. Discodea Gray, err. typ.)."

But Discoides Parkinson could be rejected only if the name were preoccupied for some other genus. This proves to be the case. L. Agassiz, in his 'Nomenclator,' under Mollusca, quoted "Discoiles, Reu.,=Plewrobranchus," giving no reference. Writers on

* Op. cit. p. 171 of original edition, p. 107 of reissue in same year. In Leske's synopsis of his own species and genera, on p. xviii, this is introduced as "Genus III. Conulus Klein. Echinites mihi." This and the fact that Echinites had already been used by Gesuer ('Tract. phys. de Petrif.' p. $34 ; 1758$ ) warrant the adoption of Conulus. The genotype is Conulus, vel Echinites, albo-galerus Leske ex Klein; but this is congeneric with Echinites, vulgaris, the genotype of Galerites Lamarck ('Anim. sans Vertèbres'' p. $346 ; 1801$ ), which therefore is a synonym of Conulus. Echinoconus A. d'Orbigny ex Breynius, is another synonym.
† "An Attempt to divide the Echinida \&c.," Ann. Philos. xxvi. p. 420 ; Dec. 1825. Many writers quote "Gray, le34," but no such paper can be found ; probably they are misled by the words "de nouvenu," in the paper by Agassiz quoted below.
$\ddagger$ Nêm. Soc. Neuchâtel, i. pp. 137 \& 186.

Mollusea seem to have ignored this, with the exception of Herrmannsen $\dagger$, who has this entry : "Discoides Renieri (? 1807. Tarol. classif.* [ ${ }^{*}=$ not seen]) teste Agass. Nom. . . . =Pleurobranchus Cuvier."

After much trouble on the part of many friends, I have at last receired, through the most kind exertions of Professor Dante Pantanelli of Modena, a clear and almost complete account of the work referred to. The author's name was Stefano Andrea Remier, of Chioggia. The title of the pamphlet in question is 'Tarola alfabetica | delle conchiglic adriatiche.' The copy in the library of Padua University-the only cops that could be seen-has lost the full titlepage; according to Carus and Engelmann (Bibliogr. Zool. p. ©31) it continued "nominate dietro il sistema di Linneo, edizione di Gmelin. s.l. 1788." Professor Pantanelli, horwever, asserts that the date is indubitably 1804 . The date 1807 , giren by Herrmannsen, refers to another pamphlet, No. 1 in Agassiz and Strickland's Bibliography, while the date 1788 may be due to a confusion with No. 5 in that Bibliography. For the present discussion it is enough to admit that any possible date is anterior to 1811.

The book is a folio and comprises two sections: Part I. pp. v -xiii, cntitled "Molluschi cioè Lamellibranchi e Gasteropodi compresi quelli terrestri" ; Part II. pp. xv-xxri, " Prospetto delle classe dei vermi ossia Molluschi-Vermi intestinali-Polipi." At the end are cight large systematic tables, preceded by a titlepage. This copy may possibly be incomplete so far as the number of tables is concerned.

The name Discoides is found only in Part II., and occurs first in line 5 on p. xvi, being the ninth in a list of genera of Mollusca, thus:-
"IX Discoide Discoides Ren. Discoide Discoide barcolante D. natans D. Branlant Renier."

At the foot of the page are various footnotes; of these (c) gives a description of the genus and (d) an account of the locomotion of the species and of its chief rariations. The author promises a more complete description of the species, with anatomical details and a figure, in a future "Saggio"; but this he never published. The descriptions here given are, however, enough to justify the name Discoides. Whether that name is a synonym of Plewrobranchus, established by Cuvier about the same time, must be left to the malacologists to determine.

The Echinoid genus therefore cannot bear the name Discoides Parkinson 1811, but must accept the modification Discoidea. The American school of purists would enforce the validity of Gray's misprint, while a contrary school would reject both Discoidea and Discorlea because of their common etymology with Discoides. The latter view, which I do not admit, might lead to the acceptance of one of the names next to be considered.

Gradually other species were described as belonging to the genus,

[^27]and in 1883 Pomel, perhaps following a suggestion by Desor*, thought it necessary to separate these from the true Discoidea ( $D$. subuculus) as a subgenus Pithodia, of which, if it were accepted, the type would be D. cylindrica $\dagger$.

Ignoring this action by Pomel, P. Martin Duncan, on p. 139 of his "Revision of the Echinoidea" $\ddagger$, proposed a similar subdivision of the genus on rery similar grounds, and erected a subgenus Echinites, of which the unique representative was $D$. subuculus. The name, as we have scen, was doubly preoccupied, indeed trebly, for Miiller and Troschel had also used it for an Asteroid. The subdivision had been anticipated by Pomel. And Duncan's method of subdivision was impossible, since $D$. subuculus is the genotype of Discoider.

Prof. J. W. Gregory, however, while properly rejecting the name Echinites, has gone further, and not merely proposed a new name, Protocyamus, "to indicate the affinity of this Echinoid with the Echinocyamus series," but has raised the form to the dignity of a genus §.

The name Protocyamus cannot stand, and it is rery doubtful whether any subdivision is required. Gregory made no attempt to rebut the arguments of Lambert, who (op. cit. 1892) pointed out that the chief diagnostic character used by both Pomel and Duncan, namely the distribution of the hydropores on the genital plates, was one that, in some genera at any rate, varied among individuals of a single species.

So far, then, the conclusion is that all the species should be left in one genus under the name Discoidea Agassiz.

As for the trivial name subuculus, the question has been raised whether it should not be subucula. Klein, Leske, and, indeed, most authors have written subuculus. Klein explains this as "KamisolKnopff" (Anglice "shirt-button"), which, however, is not a translation of subuculus, but includes the word Fibula understood, since the Conulus and Discoides of Klein are divisions of his "Sectio I. Fibula," which he explains as a S'phervila vel glomerula vestiaria. Subuculus, then, was Klein's Latin for K'amisol ; but the Latin word used by Horace and many other authors (see Facciolati and Forcellini's Lexicon) was subucula, signifying " a man's shirt," masculine enough in meaning if not in form. If no other authority for sul)uculus can be found, it seems preferable to cmploy in the Exhibition Galleries of the British Museum the spelling Discoidea subucula.

## THE ANNALS

## MAGAZINE OF Natural History.

[SEVENTII SERIES.]

No. S6. FEBRUARY 1905.
> XI.-Tew Species of Eastern Heterocera in the National Collection. By Colonel Charles Swinioe, M.A., F.L.S., \&c.

## Family Chalcosiidæ.

Chalcosia electra, nov.
ठ. Frons white, shaft of antennæ metallic blue, pectinations black; head and thorax black, covered with metallicblue scales; abdomen pale ochreous brown, with white segmental thin bands: fore wings dark greenish black, with a dark dull ochreous subapical band, like two oval spots joined together, extending from close to costa beyond the middle to near outer margin above the middle; a white space on the hinder margin, which in the type specimen is pure white and in the other is white suffused with brown: hind wings white, with a black apical border, broad at the apex and narrowing down the outer margin; in the Santabong. example with black streaks below the costa; some metallicblue scales at the base of the fore wings in the type specimen, on both wings in the other. Underside much as above, but there is much blue scaling on the basal portion of the fore wings and at the apex of both wings: body and legs white.

Expanse of wings $1 \frac{1}{2}$ inch.
1 ठ, Pewrisoen, Borneo (Shelford) (type).
1 §, Santabong, Borneo (Shelford).
I know of no near ally. Ann. \& Mag. N. Hist. Scr. 7. Vol. xv.

## Family Drepanulidæ.

## Problepsidis neoma, nov.

ठ. White, suffused with pale chestnut-brown irrorations in parts; two nearly straight brown lines from the abdominal margin of the hind wings, the first from one third, the other from the middle, run parallel across both wings and suddenly converge on the middle of vein 5 of fore wings, and run from thence in a single line to the costa near the apex; between these lines on the fore wing is a large hyaline space ; the rest of the wing is lightly suffused; on the outer margin there is a fairly broad pale pinkish band, composed of large pale pinkish spots joined together; marginal line brown ; cilia pale pinkish, marked with brown: hind wings with the inner area nearly white, the outer area from the outer line to the margin with dark suffusion, and through the middle of the diss a dentated white line ; marginal line white; cilia white and brown. Underside white, the hyaline patch on fore wings prominent, bordered outwardly by a dark brown band: lind wings with a broad dark brown band, which covers a third of the wing.

Expanse of wings $\frac{9}{10}$ inch.
Singapore (Ridley).
Allied to carneotincta, Warren, =excisa, Hmpsn.

## Problepsidis tristis, nov.

$\delta$. White; pectinations of antennæ ochreous: fore wings with a broad pale brown medial band from the middle of hinder margin to the upper end of the cell; a similar marginal band from the hinder angle to vein 6, through which runs a white dentated line: hind wings with very faint indications of two similar bands ; on the medial bands of both wings are some white, iridescent, raised scales. Underside white; fore wings with a brown land from the middle of the hinder margin, which is curved at vein 6 and runs down again to the hinder margin near the angle.

Expanse of wings 1 inch .
Matang, Borneo (Shelford).
Has the fore wing somewhat excavated below the apex, and is allied to carneotincta, Warren.

## Cullidrepana pilana, nov.

ㅇ. The upper half of the hind wings, including the entire cell, is whitish; otherwise the entire coloration of body and
wings is very uniform dark ochreous, covered with very minute iridescent white scales, and on the middle of the fore wings a few black atoms; a straight dark orange line rans from below the middle of the abdominal margin of the hind wings to near the falcated apex of the fore wings (obsolete on the whitish portion of the hind wings) ; an indistinct indication of a dentated orange submarginal line on both wings and dark marginal line and cilia. Underside of a uniform pale orange ochreous, without any markings.

Expanse of wings $1 \frac{1}{2}$ inch.
Matang, Bornco (Shelford).
Antennæ bipectinate, the branches short.

## Family Limacodidæ.

## Parasa insignis, nov.

§ 오. Of a uniform dark bright chocolate-colour; a pale spot on the palpi above near the tip; a green spot behind the base of each antenna; a green antemedial transverse band on the fore wings from before the middle of the hinder margin to the middle of the costa, narrow and broken in the male, broad and unbroken in the female, and somewhat expanded on the costa. Underside of the same uniform dark bright chocolate-colour; a whitish space on the basal half of the hinder margin of fore wings; legs with pale spots. The female is paler chocolate than the male, the hind wings and the underside considerably paler.

Expanse of wings, $\delta 1_{1}^{2}$, it 2 inches.
ठ ㅇ, Bornco, 1904 (Shelford) (types).
1 ठ, Borneo, $190 \pm$ (Shelford).
1 i, Kuching, Borneo, 1902 (Shelford).
Belongs to the lepida group.

## Family Lymantriidæ.

## Euproctis dirtea, nov.

ठ. Antennæ, palpi, head, thorax, and fore wings dark dull greyish ochreous ; palpi brown above ; shaft of antenne brown, a white spot at the base on cach side: fore wings irrorated with black atoms; a prominent black spot at the end of the cell ; two dark grey, transverse, even bands, antemedial much outwardly curved, the other discal and very slightly curved; a concolorous cilia with grey patches: hind wings dull yellow ; the abdominal area broally brownish; abdomen brownish black; anal tuft dull yellow. Underside
of a pale dull ochrcous, the abdominal area of hind wings brownish; a prominent large black spot at the end of the cell in both wings: body and legs without markings.

Expanse of wings $1 \frac{8}{10}$ inch.
Kuching, Borneo, 2 ठ (Shelford).
Belongs to the plana group.

## Family Hepialidæ.

## Palpifer pellicia, nov.

$\delta$ ㅇ. Of a uniform dull brown colour above and below, a slight red tinge on the hairs of the legs: the fore wings above have a very small white dot in the middle of the cell, which, however, is not visible in all examples; the hind wings have a moderately large yellowish spot on the outer margin below the apex; there are no other markings.

Expanse of wings ${ }_{10}^{8}-1 \frac{1}{10}$ inch.
Khasia Hills.
Allied to $P$. cerulescens, Swinhoe; paler in colour, the wings more sparsely clothed, and uniformly smaller ; ceruleacens has a prominent large white spot in the middle of the cell of fore wings and no yellow spot on the hind wings. I have five examples of this new form and have examined several others.

## Family Trifidæ.

## Caradrina pratexta, nov.

む $\circ$. Ochreous brown ; palpi with pale hairs in front; thorax with a brownish band in front; abdomen of the male with blackish-brown hairs and luteous anal tuft: fore wings variegated with pale luteous-grey marks; a pale antemedial transverse line, edged on each side with brown, a short outward angle in the middle, and bent inwards shortly on to the costa and on to the hinder margin ; a postmedial similar line, which, however, is not bent inwards at its lower end; a submarginal simuous pale line, edged on its inner side with brown; orbicular a small black spot, palestinged ; reniform black, large, somewhat ear-shaped, and ringed with a pale line: hind wings pale brown, a brown lunule at the end of the cell; marginal line pale, interrupted on fore wings: cilia of fore wings brown, of hind wings luteous, with a brown basal line. Underside grey; a brown lunule at the
end of each cell; both wings with dark grey discal lines and pale submarginal fascia.

Expanse of wings $1 \frac{4}{10}$ inch.
Khasia Hills.
'There is an example from Darjiling in the B. M., drawer 142.

## Euplexia flavistigma.

- ${ }^{2} y$ lophasia flavistigma, Moore, P. Z. S. 1867, p. 50 ; Ilmpsn. no. 171.).
-1ylophasia sodalis, Butler, Ann. \& Mag. Nat. Hist. (5) i. p. 83 ; Hmpsn. no. 1717.
Apcmea strigidisca, Moore, P. Z. S. 1881, p. 346, pl. xxxviii. fig. 9. A pamea basalis, Moore, l. c. p. 346.
Apramea denticulosa, Moore, Lep. Atk. p. 109, pl. iv. fig. 13 (1882).
Apamea obliquiorbis, Moore, l. c. p. 109.
Khasia Hills; common.
The type from Bengal is in Coll. Staudinger, but the description is good, and there can be no mistake about the identitication ; the type of sodalis from Japan is in the B. M., so are also the types of strigidisca from Sikkim, basalis from Dalhousie, and obliquiorbis from Darjiling; the type of denticulosa from Darjiling is also in Coll. Statidinger, but the description and figure are good: all the above are undoubtedly one species. Sir George Harnpson puts Hadena constellata, Moore (Lep. Atk. p. 130, pl. iv. fig. 21), from Sikkim, the type of which is also in Coll. Staudinger, as a synonym to flavistigma, but neither the description nor the figure corresponds.

## Family Acontiidæ.

## Agrophila burmana, nov.

$\delta$. Frons with a pale luteous band; thorax and fore wings luteous white; abdomen grey, with white rines: fore wings with a very broad blackish-brown marginal band, occupying nearly half the wing; this band has a clearly cut inner edge, is narrow at the apex, curves round the reniform to the middle of the wing, then almost straight down to the hinder margin; the rest of the wing is luteous white, with a medial double line, nearly erect, and some pale blackishbrown marks on the costa; marginal line whitish; the reniform is a round ringlet, the orbicular is not visible: hind wings brownish, without markings.

Expanse of wings $\frac{7}{10}$ inch.
Becling, Burma (Bingham).

I have several examples, all identical; it appears to be a good and uniform species. There is one in the B. M. from Thyetmyo, Burma, in drawer 195, with A. basifera, Walker.

## Maliattha stolasa, nov.

§ 우. White, minutely irrorated with chestnut-red atoms; palpi, frons, and antenne chestnut-red: fore wings with the costal border and outer portions suffused with that colour; some white specks on the costa; indications of two outwardly curved white lines before and beyond the middle rather close together ; a white transverse streak below the apex close to the outer margin: hind wings grey; marginal line of both wings white; cilia white, interlined with grey.

Expanse of wings $\frac{8}{10}$ inch.
Khasia Hills.
Allied to M. plumbata, Butler, from Dharmsala, which I also have from Simla; is common in the Khasia Hills. There is in the B. M. drawer 199, unnamed, one from Arjuno, Java, and one from Sarawak, which appear to me to be identical with the Khasia Hill form.

## Cerynea rubra, nov.

ठ. Palpi, frons, and head chocolate-brown; body and wings reddish-orange colour: costa of fore wings broadly chocolate-brown; two brown dots at the end of the cell ; a pale lunular mark halfway between these and the outer margin: hind wings with a brown mark in the cell, some in the middle, and some in the disk; apparently indications of transverse bands, of which there are also some indieations on the fore wings: both wings variegated with marks of darker orange ; brown marginal fistoon and black spots. Underside smoky grey, the wings crossed by three indistinct grey bands; legs brownish grey.

Expanse of wings $\frac{9}{10}$ inch.
Matang, Borneo (Shelford).
Allied to ustula, Hmpsn., from Ceylon, and superficially somewhat resembling it; but that insect has broader wings and two spots at the end of each cell.

## Rivula niveipuncta, nov.

ォ. Palpi, head, and collar pale ochreous grey; thorax and fore wings dark olive-brown; spots on fore wings pure white, subbasal, ante- and postmedial, and two close to the apex;
two white dots below the second spot, a cluster of many spots and dots below the third, three dots on the costa between the third and fourth, with two or three dots below them; a large white subbasal spot within the wing and two dots in a line beyond: hind wings and abdomen pale brown, without markings. Underside: fore wings grey, with the apical spots and some spots and dots on the outer half of the costa: hind wings whitish, with a grey spot at the end of the cell and a grey discal line.

Expanse of wings $\frac{7}{10}$ inch.
Khasia Hills.
Somewhat resembling $R$. niphosticta, Hmpsn., from Ceylon, but the spots on the fore wings are differently arranged.

## Family Palindidæ.

## Homodes irretita, nov.

on . Of a uniform dull dark fulvous, brighter than fulva,
 Guenée, or vivida, Guenée, the margins slightly darker than the interior portions of the wings ; antemedial and medial slightly waved, dark transverse lines nearly erect on the fore wings, the inner line continued on the hind wings, curving slightly outwards; duplex dentated discal lines across both wings, the inner line having black points on the dentations on the hind wings; the first three lines ending in black dots on the costa of the fore wings; duplex dark red submarginal lines on both wings, enclosing a series of small black lunular marks; black lunules close to the outer marginal black line ; all the black points and lunules with minute white points attached to them. Underside of a uniform fulvous-red colour ; fore legs with thick whitish hairs.

Expanse of wings $1_{10}^{2}$ inch.
Khasia Hills (type).
Silchar, Cachar.
There is one example in the B. M. from the Khasia Hills; there are also in the same drawer three from Fergusson Island, three from the Solomons, and three from Singapore which cannot be separated from this form. It is nearest to bracteigutta, Walker, from Sarawak, the type of which is in Mus. Uxon.

Family Sarrothripidæ.<br>Genus Nanaguna, Walker.

Nanaguna, Walker, xxvii. 85 (1803).
C'lettharra, Walker, xxvii. 101.
Orosa, Walker, xxxiv. 1222 (1865).

## Nanaguna breviuscula.

Fanayna breriuscula, Walker, xxvii. 85.
Cettherra valita, Walker, xxvii. 101 ; Impsn. no. 22:37.
Cletthura floccifera, Impsn. Moths India, ii. p. 386 (1894).
Khasia Hills : common.
Also from Nagas, Burma, Ceylon, and Borneo; very variable in shades of colour.

## Nanaguna aquisoides, nov.

$\delta$ ㅇ. Palpi brown, white at the base and tips of the last joint; frons brown; head and thorax white, the latter with brown specks; wings and abdomen dark olive-brown: fore wings with white suffusion, speckled with brown at the base and on the costal and apical areas, forming a circle round the brown portion of the wing; indications of a subbasal brown line, of a discal line outwardly angled at vein 3, and of a submarginal line, but all very indistinct; marginal line dark blackish brown: hind wings slightly pale brown, without markings. Underside dull brown, marginal line pate, no markings; tarsi with pale bands.

Expanse of wings $1 \frac{2}{10}$ inch.
Khasia Hills.
There is one example in the B. M. Deltoid drawer no. 45, without name, from the Khasia Hills; superficially this insect is much like Aquis viridisquama, Walker, xv. 1652, from Sarawak.

## Labanda viridalis, nov.

of. Frons, head, thorax, and fore wings green (the ground-colour is really white, thickly irrorated with minute green atoms) : fore wings with a broad basal black band, some green markings inside it near the base, representing the subhasal transverse line; the discoidal vein thickly black, making a prominent lunule; an antemedial, slightly dentate, black line close to the outer margin of the basal band; an ontwardly curved discal similar line, duplex in parts, a submarginal similar broken line outwardly edged with white ; a marginal black line ; cilia green, with black patches ; a black suppressed largish spot on the costa at the middle, another much larger at one third from apex, and two small ones close to the apex, and two more prominent spots below them, the lower one the larger: hind wings brown, unmarked: abdomen brown, with black and green crests. Underside
brown, without markings, except for a few pale spots on the costa of fore wings.

Expanse of wings, $\delta^{7} 1$, if $1 \frac{s}{10}$ inch.
Khasia Hills.
There is an example from the Khasia Hills in the B. M. drawer no. 44.

## Blennia fumosa, nov.

ㅇ. Palpi grey, brown-speckled; head, thorax, and fore wings chocolate-brown, with a slight greenish tinge ; transverse lines slightly darker than the ground-colour, all very indistinct-first subbasal, sinuous, and double, second just before the middle, also double, bent outwards, third similar and discal, fourth submarginal, single, and marked with white and brown dots; a broad blackish shade or diffused oblique band from the middle of the costa to the hinder margin near the angle, marginal points whitish: hind wings paler and with an ochreous tinge, blackish on the outer margin ; indications of a thin, ochreous, waved, discal band; cilia dull ochreous. Underside: body, legs, and inner half of wings pale greyish brown, outer half of wings dull black ; some dull ochreous spots on costa of fore wings towards apex; both wings crossed by a thin dull ochreous band, outwardly angled below the middle on the hind wings; cilia of both wings dull ochreous.

Expanse of wings $1_{10}^{8}$ inch.
Khasia Hills.
Not nearly allied to anything I know of; fore wings narrower and longer than is usual in the genus, outer margin rounded.

## Family Haliadæ.

Topadesa sanguinea.
Topadesa sanyuinea, Moore, Lep. Atk, p. 280 (1882).
Khasia Hills.
Moore described a male from Sikkim, the type of which is in Coll. Staudinger ; there is one male from Darjiling in the B. M.; I have now received several pairs from the Khasia Hills.

The female differs from the male in the colour of the fore wings being purple instead of fiery red, the fiery-red colour only showing on the edging of the purple; no cell-spot; the front half of the thorax is also purple and the upper part of the abdomen is smeared with pale purplish grey. 'The underside is much as in the male, cell-spot and all but the interior of the fore wing is suffused with purple.

## Family Stictopteridæ.

## Gyrtona niveivitta, nov.

ㅇ. Brorn-black ; abdomen pale black; the hind wings very slightly paler than the fore wings, the latter with a broad white subcostal stripe from the base to the outer margin a little below the apex; the upper side of the stripe even, the lower side rough; the orbicular invisible, the reniform a black ringlet, within the stripe; two submarginal sinuous white lines, well separated, pale spots on the outer margin and black crenulated line; cilia of both wings with white tips. Underside dull black, without markings.

Expanse of wings $\frac{9}{10}$ inch.
1 of, Kuching, Sarawak (type).
1 f, Penang.

## Family Gonopteridæ.

Cosmophila excarata, nov.
우. Of a uniform pale greyish chocolate-colour ; palpi on the inner sides, head, and collar white, thickly irrorated with ochreous brown: fore wings thickly irrorated with ochreous brown in parts, leaving a more or less clear space before the middle and a space at the apex: hind wings with similar irrorations on the disk, almost forming a band ; through this and up the fore wings runs a very acutely dentated submarginal line; some brown marks above the middle of the outer margin of fore wings, one at the angle, and one at the apex ; cilia of both wings pale ochreous, with white tips, interlined with brown, the interline macular on the fore wings above the angle.

Expanse of wings $1_{J_{\overline{0}}}^{7}$ inch.
Sadong, Borneo (Shelford).
I do not quite know where to put this insect without examining its male; the apex of fore wings is acute, the outer margin is produced at vein 4 and rather deeply excavated between this and the apex; the outer margin of the hind wings is slightly angled at vein 2 and is quite straight between veins 2 and 6, like a Focillid.

## Tympanistes flavescens, nov.

ठ. Antennæ, palpi, head, body, and fore wings dull pale yellow; head, thoras, and costal and basal portions of fore wings suffused with olive-green; transverse olive-green lines distinct, prominent, highly sinuous, and dentated in parts-
subbasal, antemedial, postmedial, and submarginal, the last broken and irregular; outer margin with black dots between the veins: hind wings white, with pinkish suffusion on the abdominal area. Underside pale yellowish white; costal area of fore wings suffused strongly with pink ; a brown subapical spot on the costa and another below it ; legs with brownish hairs.

Expanse of wings $1_{15}^{4}$ inch.
Khasia Hills.
Between T. testacea, Moore, and T. rubidorsalis, Moore, but the lines in these forms are not dentated, are much less sinuous, the coloration is nearly white, and the undersides have no markings whatever.

## Cavea dione, nov.

$\delta$ ㅇ. Antennæ, palpi, and frons chestnut-colour; collar and patagia purplish brown, the rest of the thorax, the abdomen, and fore wings pale creamy pink, with minute brown irrorations; these are collected densely together in parts and form subbasal, antemedial, postmedial, and submarginal oblique bands, the postmedial being the broadest and darkest, extending from a little beyond the middle of the costa to the hinder angle; there are also two transverse, brown, straight lines, the first oblique, from the middle of the costa, the other nearly crect, from the costal third to the hinder margin near the angle; cilia brown: hind wings pale pinkish, without markings. Underside pale pinkish, without markings.

Expanse of wings $1 \frac{1}{2}$ inch.
Khasia Hills.
Fore wings with the outer margin rounded. Allied to fasciata, Moore, which I have also from the Khasia Hills; but that form is of an almost uniform dark brown-pink, with discal and submarginal highly sinuous transverse lines and shorter wings.

## Family Quadrifidæ.

## Hypatra ruinosa, nov.?

ㅇ. Antennæ, palpi, head, thorax, and fore wings dark chocolate-brown; palpi whitish beneath, and speckled with white above : fore wings with the outer third smeared with a glaucous sheen; black patches on the costa; a large oval black patch on the disk, touching the glaucous band, ringed inwardly with deeper black; the black line rumning partly along the inner limit of the glaucous band; many lunular
and sinuous grey bands across the wing, more or less indistinct; a double black, sinuons, submarginal line: hind wings dark brown, the outer part more or less glaucous; two ochreous marks near anal angle; cilia dark brown, with two subapical white spots and one near anal angle.

Expanse of wings $1_{1}^{7}-11_{10}^{9}$ inch.
1 ㅇ, Singapore (type) (Ridley).
2 i, Kuching, Borneo (Shelford).
1 if, Andamans (Moore Coll.).
Allied to includens, Walker.

## Iypatra trifasciata, nov.

б. Palpi dark chestnut-hrown above, white beneath, last joint ochreous grey beneath ; head, body, and wings of a miform pale brownish grey, irrorated and striated in parts with hackish brown: fore wings crossed by three nearly erect blackish fasciee or bands, rather broad and more or less incomplete, these bands themselves containing in places small darker black patches, marginal festoon grey, points black: hind wings paler on the costal space, where there are no irrorations; indications of a discal transverse line, elbowed outwardly below the middle, where there is a black spot, marginal festoon grey, points grey. Underside ochreous grey, almost whitish, very uniform in colour, no markings ; the long hairs on the legs variegated, black and ochreous grey.

Expanse of wings $1_{1}^{7} \sigma$ inch.
1 ơ, Kapaur, N. Guinea (type) (Doherty).
1 ठ, Fergusson Island (Meek).

## Hamodes Butleri.

Thermesia (?) Butleri, Leech, Trans. Ent. Soc. 1900, p. 570.
Khasia Hills; fairly common.
I'he type came from Western China; the Khasia Hills examples are paler in colour, but are not separable.

## Family Focillidæ.

## Zethes pallidiplaga, nov.

o. Uniform greyish white, slightly tinged with ochreous; palpi brown, with pale tips; a pale chestnut-brown large patch on the thorax: fore wings with a subbasal broad band, a brown dot in the cell, a transverse sinuous line, a large almost square patch, its top touching the costa, its
lower end touching a transverse, outwardly bent, pale line; a large, also nearly square, patch on the outer margin at the apex; a submarginal grey line and brown marginal spots: hind wings with antemedial and submarginal simunus grey lines, a medial straight pale line, a large chestnat-brown patch at the anal angle.

Expanse of wings $1_{10}^{\frac{7}{0}}$ inch.
Penang (Flower) (type).
Isabel Island, Solomons (1/eek).
The Isabel example has the patches smaller, but is otherwise very similar to the type specimen.

## Zethes enigmaria, nov.

ठ 오. Dark red-brown, with an ochreous tint and variegated with ochreous patches: fore wings with ochreous dots on costa towards apex ; ante- and postmedial outwardly curred sinuous brown lines; a large ochreous spot at the end of the cell, with a thin brown lunular mark inside it; an ochreous spot in the disk in a line with the cell, another near the hinder angle: hind wings with an antemedial line, a medial line, the space between forming an ochreous band; a discal line, the outer portion of the wing mostly ochreous; the ochreous parts mostly dull in colour ; a marginal lunular line on both wings and cilia with a basal ochreous line. Underside pale pirkish grey on fore wings, ochreous on the hind wings, the former with a black subapical lunular spot on the costa; indications of medial and discal lines, the outer portion of the wing suffused with purplish brown: hind wings with an antemedial line; a broad discal black band and both wings with black marginal line; blackish cilia with ochreous basal line.

Expanse of wings $1_{10}^{4}$ inch.
Khasia Hills.
Allied to Z. perturbans, Walker.

## Family Deltoididæ.

## Talapa birthana, nov.

ㅇ. Palpi black, with whitish hairs on the upper side; head, body, and wings of a uniform pale brown, tinged with pink; thorax with a black patch; abdomen with brown segmental lines: fore wings with some short brown marks rumning along the costa; a black triangular patch before the middle below the cell, its outer side incurved, and edged with white, a black spot just above its outer end; a large black
suffused spot outside the patch nearly even with its upper side, and in this patch is a prominent white spot, with a short streak running from it obliquely upwards, and through it runs a transverse, indistinct, sinuous grey line from costa to hinder margin; a discal sinuous line, which is (except towards the costa) deep black and thick, outwardly edged with whitish, and followed by a whitish line close to it ; between this and the outer margin is another sinuous but incomplete whitish line; marginal lunules brown, with whitish points; cilia with pinkish-white streaks opposite the veins: lind wings with indications of a medial pale line and pale marginal line.

Expanse of wings $1_{10}^{4}$ inch.
Khasia Hills.
Allied to T. albigutta, Swinh.

## Adrapsa curiosalis, nov.

$\delta i$. Dark blackish brown, with a pink tinge: fore wings with a white dot in the cell, a white spot at the end, and a large white square patch near the apex, with a white streak to the costa on its inner side; both wings with a medial, slightly sinuous, transverse, white line, dentated in parts; a discal similar line rather near the margin, indistinct in parts and touching the inner side of the subapical patch ; marginal line whitish, lunular in parts. Underside rather variegated in colour; a white spot at the end of each cell; the subapical patch and transverse lines as above; antennæ, body, and legs same colour as the wings, the long hairs on the fore legs of the male pale dirty whitish ochreous.

Expanse of wings, of $1 \frac{3}{10}$, \& $1 \frac{7}{10}$ inch.
Khasia Hills.
The antennæ are somewhat as in A. albirenalis, Moore, but there is no hook at the base, as is the case in that species; one male in my collection is almost as much variegated in colour above as it is below, with a pale shade inside the medial line.

## Catada sabada, nov.

ô. Antennæ, palpi, head, and body dark olive-brown: fore wings with a broad band of the same colour, which occupies nearly the basal half of the wing, leaving a small basal space and the outer half of the wing dark pinkish grey ; the band has on each side slightly sinuous but erect white
edges ; a brown semicircular mark near the apex : hind wings and underside of a uniform dull brown, without markings.

Expanse of wings, ठ $\frac{9}{10}$, \& $11_{10}^{1}$ inch.
Goping, Perak (Kunstler).
Superficially like C. bipartita, but that form has the fore wings angled in the middle of the outer margin ; in this form the outer margin is rounded.

## Falcimala diacia, nov.

ठ ㅇ. Palpi brown on the outer side, pale on the inner side, last joint whitish, with a brown ring near the tip; frons whitish ; collar brown in the middle, white at the sides; body and wings whitish: fore wings with a black streak on the costa near the base, a large oblique black patch at the middle, the costal space from thence to the apex white; a nearly upright, broad, pale medial band from the patch to the hinder margin, the patch and band edged with white; the colour of the wing inside the band white, on the outer side it is smoky brown; a subbasal line of white specks; the extreme apex pure white; the marginal line with black points joined to very minute white specks: hind wings greyish white. Underside : fore wings pale grey, with white dots on the costa beyond the middle and at the apex: hind wings whitish.

Expanse of wings $\frac{7}{10}$ inch.
Khasia Hills.
Allied to $F$. ochrealis, Hmpsn., which is pinkish ochreous, has no medial band on fore wings, and has brown hind wings.

## Family Hypenidæ.

## Hypena regia, nov.

ㅇ. Palpi, head, and body dark greyish-olive colour: fore wings dark olive-brown; a large round prominent white spot in the middle of the cell, a black lunule at the end; a postmedial, nearly straight, black line from the hinder margin at two thirds to the costa near apex; an irregular row of indistinct submarginal dots, the four upper ones white, the remainder black; a pale shade across the disk: hind wings brownish grey, whitish towards base. Underside pale brownish: fore wings with a small cluster of white dots at the apex: hind wings with a brown lunule at the end of the cell ; both wings crossed by a medial brown line.

Expanse of wings $1{ }_{i 5}{ }^{4}$ inch.
Granville, New Guinea.
Allied to nothing I know of.

## Mypena tylistalis, nov.

ㅇ. Olive-brown, with a pink tinge. fore wings with erect transverse lines, antemedial and slightly sinuous, postmedial and quite even, composed of two colours, the inner brown, the outcr white; the whole imer space from this to the base darker than the rest of the wing; a sinuous line adjoining, followed by a nearly straight submarginal line: hind wings without markings, marginal line of both wings black; cilia with a white basal line. Underside much paler: fore wing; with a white subapical spot: hind wings with a brown spot at the end of the cell and a brown discal line.

Expanse of wings $1 \frac{1}{2}$ inch.
Granville, New Guinea.
Allied to II. umbripennis, Moore, from India, of which I have a good series; but that form has all its lines sinuous.

## Hypena phecomalis, nov.

$\delta$. Dark olive-brown; palpi white at the end of the last joint: fore wings with an erect, almost straight, brown line, outwardly edged with whitish beyond the middle, the entire space inside it dark blackish brown, and contains a darker spot at the end of the cell and a darker basal band, with its outside edge acutely dentated outwards, below the middle ; a dark brown shade below the apex, leaving a paler space on the costa near the apex; faint indications of a row of submarginal pale dots and white points on the margin: hind wings without markings. Underside pale brown, tinged with pink: fore wings with indications of postmedial and submarginal lines : hind wings with a black spot at the end of the cell, and medial and discal lines.

Expanse of wings $1 \frac{1}{2}$ inch.
Khasia Hills.
Wings broader than is usual in the genus, the hinder angle more rounded, costa of fore wings rounded near the base. There are two examples from the Khasia Hills in the B. M. with $H$. tenebralis, Moore, of which I have a fine series; but it is quite distinct from that form, being a much broader insect, with the lines erect instead of oblique.

## Family Boarmiidæ.

## Heteromiza obliquaria.

Anzea obliquaria, Leech, Ann. \& Mag. Nat. Hist. (6) xix. p. 182 (1897).

Khasia Hills.

Leech's type came from thang Yang, Central China. I have six from the Khasia Ilills, and there is an example in the B. M. marked "India" from Dr. F. Moore's collection; they are absolutely identical with the Chinese examples.

## Family Sterrhidæ.

Chrysocraspeda fulviplaga, nov.
o ㅇ. Orange-pink, tinged with purple: fore wings with a prominent black spot at the end of the cell ; an antemedial, transverse, yellow line, angled slightly outwards in the cell; a discal similar line, angled outwards at the middle, its lower half obscured in the male by a large patch of purplish suffusion, which extends on the lower half of the wing from the inner line to the outer margin: hind wings with a yellow subbasal line, much angled outwards at its middle; a very large triangular yellow patch, occupying nearly the whole of the disk; a discal yellow line like that on the fore wings, the upper prortion of it being only visible, the lower portion being merge: in the discal yellow patch; cilia of both wings bright yellow. Underside: fore wings pink-red, with the outer and hinder margins yellow: hind wing with the imer half pinkred, the outer half yellow; frons white; antemme, body, and legs pink-red; ablomen with the tips and the whole of the underside whitish.

Expanse of wing's, $\boldsymbol{\sigma}^{7} \frac{9}{10}$, 아 $1 \frac{2}{10}$ inch.
Khasia Hills.
Belongs to Hampson's Section I. B, and is allied to iole, Swinhoe; the hind wings resemble those of dilucida, Warren, but that form has no transverse lines.

## Chrysocraspeda conspicuaria, nov.

$\delta$ ㅇ. Pale pink, irrorated in parts with brown atoms; costa of fore wings brownish; a large black spot at the end of the cell, three or four black points in a row outside the cell: hind wings with a pure white elongated spot at the end of the cell; a discal row of black points; outer margin of both wings with a conspicuous brown band and bright yellow cilia. Underside of a uniform dark red-pink; cell-spots as above, Lut less distinct; costa of fore wings blackish brown; no outer marginal band to either wing; cilia yellow; frons white; antenne and body above pink-brown; body beluw and legs whitish.

Expanse of wings $\frac{9}{10}$ inch.
Khasia Hills.
Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.

Fore wings with the apex produced and acute; hind wings with the outer margin rounded. Belongs to Hampson's Section I. $b$, and is allied to abhadraca, Walker; but the markings are much as in sanguinaria, Warren.

## Family Geometridæ.

## Actenochroma ochreipicta, nov.

$\delta$. Frons ochreous, with a green centre ; head, body, and wings green, irrorated and striated with olive-green; an indistinct blurred dark spot at the end of each cell: fore wings with indications of antemedial and discal darker bands, the hinder margin with two ochreous spots, ante- and postmedial, and another in the disk above the middle ; inside the outer band there is a dentated black line visible in places, but very indistinct: hind wings with a similar line, more distinct, and indications of both bands; an ochreous spot on the abdominal margin at the end of the outer band; marginal lunules black; cilia ochreous in parts. Underside pinkish white ; a prominent black spot at the end of each cell and a broad blackish discal band, with some blackish suffusion between it and the outer margin; marginal lunules black.

Expanse of wings $1_{10}^{8}$ inch.
Khasia Hills.
Of the shape and size of $A$. viridaria, Moore, but the colour is darker, more olive-tinted, and quite different.

## Agathia ithearia, nov.

$\delta^{\text {r. }}$. Antennæ, palpi above, head, and body pale chocolatecolour ; palpi below white; frons with the lower half white, upper half chocolate; thorax with two large green spots in front: wings green, bands chocolate-colour; fore wings with a band at the base, a narrow costal band, and both wings with a broad marginal band; on the fore wings there is a thin sinuous band from the middle of the costa to the hinder margin, touching the marginal band; within the latter is a large green subapical spot, with a small spot above and two below it: a large green oval spot on the hind wings within the marginal band, touching the outer margin below the apex, and a pale streak which runs downwards a short distance: on both wings the marginal band is lined on both sides with dark chocolate and edged on the inner side with whitish.

Underside greenish white, with a broad, sinuous, discal band of pale chocolate-colour across both wings.

Expanse of wings $1_{\mathrm{T}^{4} 0}$ inch.
Kuching, Borneo (Shelford).
Nearest to carissima, Butler, from Japan.

## Agathia solaria, nov.

$\delta$. Antenne, upper side of palpi, upper half of frons, thorax above, and bands on both wings chocolate-colour, lower side of palpi and lower half of frons white; a green band behind the base of the antennæ, a broader green collar, a green spot on the hind part of the thorax; abdomen with the apical third pale, nearly white, the tip chocolate: wings green; fore wings with a narrow costal band, very pale chocolate; a sinuous submarginal band, broad and curved and dark chocolate (nearly black at the apex), touching a black spot on the outer margin below the apex, then continued, thin, pale, and sinuous, to the hinder margin near the angle; black elongated spots on the margin at the ends of the veins, followe 1 by chocolate spots on the ochreous-grey cilia; a narrow chocolate band at the base, which does not reach the costa, which here is green ; this band is continued thinly down the abdominal margin of the hind wings (with a spot in the middle) until it reaches the broad outer marginal band, which is broad at the anal angle, narrowing upwards, contains a green spot where the abdominal band joins it, and a larger green spot below the apex, which is narrow and runs down the margin a little; this outer band on both wings contains on its inner margin an acutely dentated dark line with the points black and pointing outwards, on the fore wings obsolete on the thin part of the band; marginal line of hind wings chocolate, cilia ochreous grey, with chocolate spots at the vein-ends. Underside greenish white; bands nearly black, on fore wings more or less as above, on the hind wings nearly uniform in breadth.

Expanse of wings $1_{10}^{40}$ inch.
Singapore (Ridley).
There are some indistinct chocolate marks in the middle of the wings that look like obsolete bands, but they are not traceable; the insect belongs to the hemithearia group.
XII.-List of the Snakes in the Zoological Nuseums of Lund and Malmö, with Descriptions of new Species and a new Genus. By Nils Rosén, Zool. Inst. Lund.
[Plates XI. \& XII.]
At the request of the Director of the Zoological Museum of Lund, Prof. D. Bergendal, I have determined and revised the collections of snakes in that Museum. The specimens not determised belong principally to collections made by Dr. Hj. Möller in Java (1897), by Dr. N. Holst in West Australia (1897), and by Bar. Eggers in Ecuador. Through the kindness of Dr. H. Wallengren I have further had the opportunity of examining some suakes in the Muscum of Malmö. I have found five species and one genus not previously described. A description of these and notices respecting some specimens which differ from the typical examples form the subject of this paper. As regards the systematic classification and nomenclature, I have followed G. A. Boulenger, 'Catalogue of the Suakes in the British Museum,' vols. i.-iii. (1893-96). Some snakes were presented by private individuals, without any information as to habitats.

## Fam. Typhlopidæ.

1. Typhlops braminus, Daud.

Java.
2. Typhlops bicolor, Ptrs. West Australia.
3. Typhlops olivaceus, Gray. West Australia.

## Fam. Boidæ.

4. Python reticulatus, Schn. Java.
5. Python molurus, L.
6. Epicrates cenchris, L. 14 upper labials.
7. Epicrates striatus, Fisch.
8. Corallus caninus, L.

Maroni (Surinam).
9. Trachyboa gularis, Ptrs., var. multimaculata, nov.

Snout scarcely prominent. Upper head-scales small, convex, keeled. Eye bordered by 2 labials (sixth and seventh) and 11 scales. 25 scales round the upper lip. Four pairs of shields bordering the mental groove. Scales strongly keeled, in 31 rows. Ventrals 146. Anal entire. Subcaudals 29. Brown above, with a dorsal series of large irregular black spots; two series of smaller ones on each side; yellow beneath, with large black spots.

Total length 320 mm. ; tail 35.
Ecuador.
A single specimen, belonging to the Museum of Lund, collected by Eggers, 1892, in Balao (Ecuador).

Cf. Proc. Zool. Soc. of London, 1898, p. 115, where Boulenger describes a specimen from Ecuador differing by having the eye completely surrounded with 14 scales, labials being excluded.
10. Eunectes murinus, L.

Brazil.
11. Boa constrictor, L.

Fam. Ilysiidæ.
12. Ilysia scytale, L.
13. Cylindrophis rufus, Laur.

Java.

## Fam. Xenopeltidæ.

14. Xenopeltis unicolor, Reinw.

Sumatra.
Fam. Colubridæ.
Series Aglypild.
15. Acrochordus javanicus, Hornst.

Java.
16. Polyodontophis geminatus, Boie.

Differs from the description in Cat. Snakes in having 8 upper labials, third, fourth, and fifth entering the eye.

Java.
17. Tropidonotus ordinatus, L., var. infernalis.

Oregon.
18. Tropidonotus ordinatus, L., var. sirtalis.

Oregon.
19. Tropidonotus saurita, L.

Total length of one specimen 970 mm . ; tail 290.
North America.
20. Tropidonotus natrix, L.

Sweden.
21. Tropidonotus trianguligerus, Boie.

Java, Sumatra.
22. Tropidonotus piscator, Schn., type C.

Scales sometimes feebly keeled or nearly smooth, reminding
one of Tr. Sancti-Johannis (see Boul. Cat. Snakes, i. p. 230). Java.
23. Tropidonotus tessellatus, Laur.

South Europe.
21. Tropidonotus viperinus, Latr.

Algiers.
25. Tropidonotus Clarkii, B. \& G.
26. Tropidonotus tigrinus, Boie.
27. Tropidonotus vittatus, L.

Java.
28. Tropidonotus subminiatus, Schleg.

Some specimens with third and fourth upper labials entering. the eye.

Java.
29. Helicops angulatus, L.
30. Helicops modestus, Gthr.
31. Helicops leopardinus, Schleg.

The last two species differ from the descriptions by not having any hypapophyses in the posterior region of the dorsal column. In II. leopardinus, Schleg. (which is represented in the Lund Museum by a single specimen), the lower surface of the dorsal vertebre in the posterior region has a lower kicel (text-fig. 1, a), without any crest or tubercule projecting
below the condyle. In $H$. modestus, Gthr. (two specimens in the collections), the lower surface is smooth (fig. 1, b).

In the 'Catalogue of Snakes' Boulenger has laid stress upon the presence or absence of hypapophyses on the posterior dorsal vertebre, and, so far as I know, he has continued to do so. Among the snakes I have had an opportunity of examining I have, however, found several specimens which differ from species already described only by the presence or absence of the hypapophyses in the posterior region of the dorsal column. That these ought not to be regarded as new species or genera is quite certain, and consequently the hypapophyses are not of such great importance for classification as has been supposed. More extended examination of other species and genera is required.

Fig. 1.

Vertebre in the posterior region of the dorsal column.
a. Melicops leopardinus, Schleg.
b. - modestus, Githr.
c. Tretanortious intermedius, sp. n.
d. Chrysopelea ornata, Shaw, type A.
32. Tretanorhinus intermedius, sp. 11. (Pl. XII. fig. 2.)

Without any hypapophyses on the posterior dorsal vertebres (text-fig. 1, c).

Nasals separated. Internasals small. Frontal much shorter than the parietals. One loreal, about twice as long as deep. T'wo præoculars. Two postoculars. Temporals $1+2$. Eight upper labials, fourth entering the eye. Five lower labials in contact with the anterior chin-shields. Posterior chin-shields separated from each other by scales. Scales in 21 rows, striated, with short but strong keels. Ventrals 142. Anal divided. Subeaudals 56. Dark brown above, with a dorsal series of irregular black spots, sometimes confluent. An indistinct yellow, dark-edged, lateral streak.

Yellow beneath, with brown dots, auteriorly dark, with an indistinct black median line.

Total length 520 mm . ; tai 120 .
Central America.
33. Elapoides fuscus, Boie.

Nasal entire.
Java.
34. Lycodon aulicus, L.
35. Lycodon subcinctus, Boic.

Java.
36. Zamenis horros, Schleg.

Java.
37. Zamenis constrictor, R.

Eight upper labials, fourth and fifth entering the oyc.
North America.
38. Zamenis flagelliformis, Laur.

South Carolina.
39. Zamenis gemonensis, Laur., var. asianus.

Entirely black.
40. Zamenis algirus, Jan.

Algiers.
41. Zamenis hippocrepis, L.

Algiers.
42. Drymobius bifossalus, Raddi.

Loreal longer than deep. Frontal shorter than the parietals. Total length 1720 mm . ; tail 500 .
43. Drymobius Boddaertii, Sentz.
44. Coluber fasciatus, sp. n. (Pl. XI. fig. 2.)

Rostral broader than deep. Intemasals much shorter than the prefrontals. Prafrontals large. Frontal once and two thirds as long as broad, much longer than its distance from the end of the snout. Nasal entire. Loreal a little longer than deep. One præocular. Two postoculars. T'emporals $2+2$. Eight upper labials, third, fourth, and fifth entering the eye. Five lower labials in contact with the anterior chin-shields. Posterior chin-shields in contact anteriorly.

Scales smooth, in 17 rows, with two apical pits. Ventrals without or with a rather indistinct lateral keel, 179. Anal divided. Subcaudals 100, in two rows. Dark brown above, with narrow indistinct white (in spirit) cross-bands, extending on the ventrals. These bands are caused by large white edges to the scales. Lighter beneath. Head with white streaks and spots.

Total length 305 mm. ; tail 30.
Ecuador.
A single specimen, belonging to the Museum of Lund, collected by Eggers in Balao (Ecuador), 1892.
45. Coluber letus, B. \& G.

North America.
46. Coluber obsoletus, Say.

Scales rather feebly keeled.
North America.
47. Coluber oxycephalus, Boie.

Java.
48. Coluber melanurus, Schleg.

Java.
49. Herpetodryas carinatus, L.
50. Dendrophis pictus, Boie.

Java.
51. Dendrophis formosus, Boie.

Java.
52. Dendrelaphis subocularis, Blyr.

Java.
A single specimen, ventrals 160 .
53. Dendrelaphis caudolineatus, Gray.

Java.
Five specimens, collected by Dr. Hj. Möller, 1897 The genus Dendrelaphis had not previously been found in Java.
54. Gastropyxis smaragdina, Schleg.
55. Leptophis occidentalis, Gthr.
56. Dromicus antillensis, Schleg.

West Indies.
57. Dromicus rufiventris, D. \& B.

West Indies.
58. Liophis albiventris, Jan, type A.

Ecuador.
59. Liophis pocilogyrus, Wied.

Argentine.
60. Liophis typhlus, L.

Brazil.
61. Liophis epinephelus, Cope.
62. Liophis regince, L.

Brazil.
63. Liophis parvifrons, Cope.
64. Xenodon Merremi, Wagl.

Brazil.
65. Heterodon platyrhinus, Latr.

T'wo specimens have scales very feebly keeled, but do not differ in other structural characters. United States of America.
66. Aporophis lineatus, L.
67. Rhadincea anomala, Gthr.

Argentine.
65. Rhadincea cobella, L.
69. Rhadineea fusca, Cope.
70. Urotheca lateristriga, Berth.

Ecuador.
71. Dimades plicatilis, L.
72. Coronella austriaca, Laur. Europe.
73. Coronella triangulum, Daud., type A. North America.
74. Cemophora coccinea, Blumenb. The supraoculars fused with the frontal.
75. Simotes octolineatus, Schn.

Java.
76. Contia vernalis, IIarl.

Total length 580 mm .
North America.
77. Homalosoma lutrix, L.
78. Petalognathus nebulatus, L.

Brazil.
79. Carphophis amoenus, Say. North America.
80. Calamaria Linnci, Boie.

Java.

## Series Opistiloglypifa.

81. IHypsirlina enhydris, Schn., type A.

East Indies.
S2. Homalopsis buccata, L.
Java (one specimen with a length of 840 mm . from the snout to the anal ; tail stumped) ; East Indies.
83. Cerberus rhynchops, Schn.
84. Gerardia Prevostiana, Eyd. \& Gerv.
85. Eteirodipsas colubrina, Schleg.

Internasals shorter than the praffrontals. Three preoculars, upper largest and reaching the frontal. Three suboculars ; three postoculars. Temporals $2+2$. Eight upper labials. Scales in 27 rows. Ventrals 213. Anal divided. Subcaudals 80, the anterior single. Brown above, yellow beneath; with irregular black or dark brown spots; the posterior ventrals with dark brown or black dots.

Total length 710 mm . ; tail 130.
Madagascar.
A single specimen belonging to the Museum of Lund.
86. TVimorphodon liscutatus, D. \& B.
87. Lycognathus cervinus, Laur.
88. Dipsadomorphus multimaculatus, Boie.

Java.
89. Leptodira personata, Cope.
90. Leptodira albofusca, Lacép.
91. Leptodira annulata, L.
92. Oxyrhopus petolarius, L.

94. Oxyrhopus clolia, Daud.
95. Thamnodynastes Nattereri, Mik.

Subcaudals 80 .
Brazil.
96. Thamnodynastes punctatissimus, Wagl.
97. Tomodon ocellatus, D. \& B.
98. Philodryas astivus, Schleg.

Total length 1300 mm .
99. Philodryas viridissimus, L.
100. Philodryas Olfersii, Licht.
101. Philodryas Schotti, Schleg.
102. Trimerorhinus rhombeatus, L.
103. Coelopeltis monspessulana, Herm.

Algiers.

> Anisodon, gen. nov.

Hypapophyses throughout the vertebral column, represented on the posterior dorsal vertebre by a well-developed crest, projecting below the condyle. Solid maxillary teeth anteriorly small, increasing in size and followed by an interspace, after which the teeth are very small; the last two large and grooved, situated below the posterior border of the eye. Mandibular teeth unequal, the anterior largest and separated from the rest by a short interspace. Head distinct from neek. Snout pointed. Eye rather large. Body cylindrical. Tail moderate. Scales smooth, in 17 rows. Subcaudals in 2 rows.

Java.

> 104. Anisodon Lilljeborgi, sp. n.* (Pl. XI. fig. 3.)

Rostral much broader than deep. Internasals as long as broad, shorter than the prefrontals. Nasal entire. Loreal

* I take the liberty of naming this snake after the celebrated Swedish zoologist Prof, W. Lilljeborg, who has determined the old collections of snakes in the Museum of Lund.
irregular. Frontal nearly twice as long as broad, longer than its distance from the rostral, nearly as long as the parictals. One preocular. Two postoculars. Supraocular large. T'emporals $2+2$. Eight upper labials; second and third reaching the proocular; third, fourth, and fifth entering the eye. Three lower labials in contact with the anterior chin-shields.

Fig. 2.

Anisodon Lilljeborgi, gen. et sp. n.
a. Maxillary and anterior part of the mandible.
b. Hypapophysis in the posterior region.

Scales smooth, in 17 rows. Ventrals 156-159. Anal entire. Subcaudals 43-50, in two rows. Greyish brown ; a dorsal series of lighter spots, edged with black, indistinct posteriorly. Yellowish heneath, with irregular dark spots. Head with lighter and darker irregular streaks and dots. Along the upper labials a white streak, edged with black.

Total length 490 mm. ; tail 95.
Java.
'Two specimens, belonging to the Museum of Lund, collected by Dr. Hj. Möller in Tjibodas (Java), 1897.
105. Macroprotodon cucullatus, Geoffr.

Algiers.
106. Dryophis xanthozona, Boie.

## Java.

In the 'Catalogue of Snakes,' vol. iii. (1896), Boulenger says :-" Anal entire (rarely divided)." Of the ten specimens which are preserved in the collections no less than nine have the anal divided.
107. Dryophis prasinus, Boie.

Java.
108. Oxybelis acuminatus, Wied.
109. Chrysopelea ornata, Shaw, type A. (Pl. XI. fig. 1; and text-fig. 1, $d$, p. 171.)
Hypapophyses present throughout the vertebral column,
represented on the posterior dorsal vertebra by a well-developed crest, projecting below the condyle. Ventrals 222. Subcaudals 131 .

Sumatra.
A single specimen, belonging to the Muscum of Malmö, collected by C. Richter, 1895.
110. Chrysopelea ornata, Shaw, type D.

## 111. Erythrolamprus AEsculapii, L. <br> South America.

## 112. Homalocranium melanocephalum, L.

Ecuador.

## Series Proteroglypha.

## 113. IIydrus platurus, L.

Coast of Java.
The two specimens belonging to the Museum of Lund have respectively 51 and 59 scales round the body. In the 'Cat. of Snakes' Boulenger states the scale-rows of this snake to be 45 to 47 . The two specimens also differ from the description in 'Cat. Snakes' by having the frontal shorter than the parietals. In coloration they agree with the type $\mathbf{E}$.
114. Hydrophis gracilis, Shaw.
115. Enhydris IIardwickii, Gray. (Pl. XII. fig. 1.)

One specimen, with six very feebly grooved small maxillary teeth.

## 116. Distira longissima, sp. n.

Head moderate. Body much elongated. Rostral about as broad as deep. Nasals shorter than the frontal, more than twice as long as the suture between the praefrontals. Frontal a little more than twice as long as broad, as long as its distance from the end of the snout, shorter than the parietals. One præocular. Two postoculars. Two anterior temporals. Eight upper labials; third, fourth, and fifth entering the eye, second largest and reaching the prefrontal. 'I'wo pairs of chin-shields; posterior a little longer than the anterior, in contact anteriorly. Scales smooth, imbricate, 31 round the neck, 35 round the middle of the body. Ventrals 320 , smooth. Greyish green, with dark cross-bands, broadest on the middle, narrowing on the sides.
'Total length 1650 mm. ; tail 120.
Habitat unknown. A single specimen belonging to the Museum of Lund.
117. Aipysurus australis, Sauw.

Australia.
Ventrals 167-168.
118. Platurus colubrinus, Schn.
119. Denisonia superba, Gthr.

Australia.
One specimen differs from the description of the genus Denisonia in having the poison-fangs followed by 7 small solid teeth. Boulenger states (Cat. Snakes) the number to be 3 to 5 .

## 120. Denisonia Gouldi, Gray.

West Australia.
121. Denisonia fasciata, sp. n.

Eye moderate. Rostral broader than deep, visible from above. Internasals shorter than the præfrontals, broader than long. Frontal once and one fourth to once and one third as long as broad, shorter than its distance from the rostral, shorter than the parietals, much broader than the supraoculars. Nasal entire, narrowly in contact with the præocular. Two postoculars, upper in contact with the parietal. Six upper labials, second and third in contact with the proocular, third and fourth entering the eye. Temporals $2+1$ or 2 , lower anterior wedged in between the fifth and sixth upper labials. Three lower labials in contact with the anterior chin-shields. The posterior chin-shields separated by scales, about as long as the anterior. Scales in 17 rows. Ventrals 153-165. Anal entire. Subcaudals 28-31. Yellow (? in spirit), with large indistinct brown spots or cross-bands.

Total length 410 mm . ; tail 47.
West Australia.
Two specimens, belonging to the Museum of Lund, collected by Dr. N. Holst, 1897.

Seems to be closely allied to D. maculata, Stdr.
122. Rhynchelaps Bertholdi, Jan.

West Australia.
123. Rhynchelaps fasciolatus, Gthr.

West Australia.
124. Bungarus fasciatus, Schn. Java.

## 125. Bungarus candidus, L.

Java.
Of the eight specimens in the collections there are seven with dark amnuli on the tail (not cross-bands). Frontal shorter than its distance from the rostral. The coloration on the head a little variable.
126. Naia melanoleuca, Hallow., type $\Lambda$.

Gaboon.
Some scales with white dots and edges.
127. Naia tripudians, Merr., var. leucodira.

Java.
One black specimen.
128. Doliophis bivirgatus, Boie, type C.

Java.
129. Doliophis intestinalis, Laur., f. typica.

Java.
130. Elaps fulvius, L., type A.

North America.
131. Elaps Spixii, Wagl.

Brazil.
132. Elaps frontalis, D. \& B.

Argentine.
133. Elaps lemniscatus, [.

## Fam. Amblycephalidæ.

## 134. Dipsas infienalis, sp. n.

Maxillary with 12 teeth. Rostral as deep as broad. Internasals broader than long. Præfrontals much longer than the internasals, entering the eye. Nasal entire. One preocular. 'Two postoculars. No loreal. Frontal small, broad anteriorly, much shorter than the parietals. Temporals $1+2$, very small. Nine upper labials, third, fourth, and fifth entering the eye. First lower labial in contact with its fellow behind the symphysial. Two pairs of chin-shields, the posterior largest. Five lower labiais in contact with the anterior chin-shields. Scales smooth, in 15 rows, vertebral row cnlarged. Ventrals 193. Anal entire. Subcaudals 99,
in two rows. Colour? (in spirit), with dark cross-bands, extending on the ventrals.

Total length 390 mm . ; tail 100.
A single specimen, belonging to the Museum of Lund. Mabitat unknown.

## Fam. Viperidæ.

135. Vipera beras, L.

Europe.
136. Cerastes cornutus, Forsk.

Algiers.
137. Ancistrodon rhodostoma, B sie.

Java.
138. Lachesis lanceolatus, Lacé?.

West Indies.
One specimen with small shiells on the anterior part of the head.
139. Lachesis atrox, L.

Maroni.
140. Lachesis alternatus, D. \& B.

One specimen with a 不-shaped light marking.
141. Crotales terrificus, Laur.

Well-developed shields between the internasals and the preffontals.
142. Crotalus horvidus, L.

Enplanation of the plates.

XIII.-A Synopsis of the Species of the Silurid Genera Parexostoma, Chimarrhichthys and Exostoma. By C. 'Tate Regan, B.A.

The fishes which have usually been placed in the genus Exostema of Blyth fall into three very distinct groups, which should be regarded as genera, as will be apparent from the following synopsis:-

> I. Teeth all pointed, those of the upper jaw forming a band, which is produced backwards at the sides; gill-openings extending on to the lower surface of the body ; fold of the lower lip broadly intermpted; pectoral with 11 branched rays..
> Pectoral extending $\frac{2}{3}-\frac{3}{4}$ of the distance from its
> base to the base of ventral; caudal peduncle 3 times as long as deep
> Pectoral extending $\frac{1}{2}-\frac{3}{5}$ of the distance from its base to the base of ventral; caudal peduncle twice as long as deep
> [yen. nov. Parexostoma,
> 1. P. Stoliczke, Day.
> - $P$ [Regan.
> 2. P. maculatum,
II. Teeth all pointed, those of the upper jaw forming a band which is not produced backwards at the sides; gill-openings not extending on to the lower surface of the body; fold of the lower lip contimuous or

「Saur. not; pectoral with 13-19 branched rays.. Cmmarminchithes, A. Lower angle of gill-opening below the middle of the base of pectoral, which fin extends about to the base of ventral ; fold of the lower lip not continuous.
Pectoral with 13 or 14 branched rays; caudal peduncle much longer than deep

1. C. Davidi, Sauv.

Pectoral with 16 or 17 branched rays; caudal peduncle about as long as deep
2. C. Blythii, Day.
B. Lower angle of gill-opening opposite the middle of the base of pectoral.
Pectoral with 14 or 15 branched rays, not reaching the rentral; fold of the lower lip not continuous
3. C. Fere, Vincig.

Pectoral with 19 branched rays, "extending beyond the base of the rentral; fold of the lower lip continuous
[Vincig.
4. C. macropterus,

1II. Each jaw with 2 bands or patches of small pointed teeth. with an enlarged outer series of compressed obtuse teeth; gillopenings not extending on to the lower surface of the body; fold of the lower lip continuous; pectoral with $10-12$ brauched rays

Exostoma, Blyth.
A. Caudal fin truncate or very slightly emarginate.

Origin of dorsal posterior to the extremity of pectoral ; anal with I 5 rays
Origin of dorsal above posterior $\frac{1}{3}$ of pectoral;
anal with I 7 rays

1. E. Vinciguerre,
[Regan. [Day. 2. E. Andersomi,
B. Caudal fin forked or rather deeply emarginate.
[Blyth.
Pectoral with 10 branched rays ................ 3. E. Berdmorii,
Pectoral with 12 branched rays
2. E. labiatum,
[MacClell.

## Parexostoma.

## 1. Parexostoma Stolicake.

Exostoma Stoliczk.e, Day, Proc. Zool. Soc. 1876, p. 782; Second Yarkand Mission, Ichthyology, p. 1, pl. i. fig. 1 (1878); Fishes of India, p. 502, pl. cxrii. fig. 3 (1878).

Exastoma Oschanini, Herzenstein, Bull. Ac. St. Petersburg, xxxiii. 1890, p. 120.
Hab. Eastern TMurkestan.

## 2. Parexostoma maculatum, $\mathrm{sp} . \mathrm{n}$.

Depth of body about 6 in the length, length of head nearly 4. Head as broad as long. Eyes small. Snout as long as postorbital part of head and $1 \frac{1}{2}$ the interocular width. Nasal barbel extending to eye, maxillary barbel to base of pectoral, outer mandibulary barbel to gill-opening. Dorsal I 6, commencing slightly in advance of the extremity of pectoral ; adipose fin as long as or longer than its distance from the dorsal. Anal I 5. Pectoral with 11 branched rays, extending $\frac{1}{2}-\frac{3}{3}$ of the distance from its base to the base of ventral. Ventral with 5 branched rays. Caudal truncate. Caudal peduncle twice as long as deep. Olivaceous, with numerous irregular dark spots; caudal with a white posterior margin.

Two specimens, 210 and 255 mm . in total length, from Lhasa, 'libet, collected by Capt. H. J. Walton.

## Chimarrhichthys.

Chimarrichthys, Sauvage, Rer. et Mag. Zool. xxv. 1874, p. 332.

## 1. Chimarrhichthys Davidi.

Chimarrichthys Davidi, Saurare, Rev. et Mag. Zool. xxv. 187t, p. 3i3.3. Erostoma Dacidi, Guinth. in l'ratt, Snows of Thibet, Appendix, p. 2ts (1892).

Ilab. Eastern 'libet.

184 On the Genera Parexostoma, Chimarrhichthys, de.

## 2. Chimarwhichthys Blythii.

Erostoma Blythii, Day, Prnc. Zool. Soc. 1869, p. 520 ; Fishes of India, p. 501, pl. cxvii. fig. 2 ( 10 í8).

Hal. Northern Bengal.

## 3. Chimarrhichthys Fee.

Exostoma Fete, Vincig. Aun. Mus. Genov. xxix. 189), p. 250, pl. viii. fig. 6.
ILab. Karenni IIills, Upper Burma.

## 4. Chimarrlichthys macropterus.

E.rostoma macropteram, Vincig. Ann. Mus. Genov. xxix. 1890, p. 253, pl. viii. fig. 5.
IIab. Khakhyen IIills, Upper Burma.

## Exostoma.

Exostoma, Blyth, Journ. As. Soc. Bengal, xxix. 1861, p. 155; Günth. Cat. Fish. iv. p. 264 (1864).

## 1. Exostoma Vinciguerra, sp. n.

Erostoma labiatum (non MacClell.), Vincig. Ann. Mus. Genov. xxix. 1890, p. 252.
Depth of body about $7 \frac{1}{2}$ in the length, length of head 5. Head as broad as long. Diameter of eye 2 in the interocular width, which is $3 \frac{1}{4}$ in the length of head. Snout twice as long as postorbital part of head. Nasal barbel extending to posterior margin of eye, maxillary barbel to anterior $\frac{1}{3}$ of pectoral. Outer mandibulary barbel not extending to base of pectoral; inner mandibulary barbel very small. Fold of the lower lip continuous. Lower angle of gill-opening at the level of the base of the pectoral spine. Dorsal 16 , commencing behind the extremity of pectoral ; adipose fin long and low, extending on to the caudal. Aual I 5. Pectoral with 10 branched rays, extending $\frac{3}{5}$ of the distance from its base to base of ventral. Ventral with 5 branched rays, not reaching the vent. Caudal very slightly emarginate. Caudal peduncle twice as long as decp. Uniformly brownish; fins pale.

A single specimen, 80 mm . in total length, from the Khakhyen Hills, Upper Burma, collected by the late L. Fea.

## 2. Exostoma Andersonii.

E.xastoma Andersonii, Day, Proc. Zool, Soc. 1869, p. 521.

Hab. Yunnan.

## 3. Exostoma Berdmorii.

Erostoma Berdmorei, Blyth, Journ. As. Soc. B ngal, xxix. 1861, p. ] 1 an; Guinth. Cat. Fish. v: p. 265 (1864); Day, Proc. Zool. Soc. 1869, p. 526 ; Fishes of India, p. 502 (1878).

Hab. Tenasserim.

## 4. Exostoma lebiatum.

Glyptosternm labiatus, MacClell. Journ. Nat. IIist. Calcutta, ii. 1842, p. 588.
E.rostoma labiatum, Giünth. Cat. Fish. v. p. 265 (1864); Day, Proc. Zool. Soc. 1869, p. 526 ; Fishes of India, p. $\tilde{0} 02$ (1878).
Ilah. Assam.

XIS.—Descriptions of Five new Cyprinid Fishes from Lhasa, Tibet, collected by Captain 11. J. Walton, 1.M.S. By C. 'late Regan, B.a.

During the recent expedition to Tibet, Captain H. J. Walton made a small collection of fishes, which he has forwarded to the British Museum. Of seven species represented, six appear to be new to science, the exception being Nemachilus Stolickzer, Day. This result is not surprising, for I believe that fishes have not before been described from this part of the Brahmaputra system. Five Cyprinid fishes are described below, whilst a new Silurid, Parexostoma maculatum, is described on p. 183.

## 1. Schizopygopsis Younghusbandi.

Pharyngeal teeth $5: 3-3: 4$, cylindrical, obtusely pointed, those of the outer series slightly curved inwards. Depth of body $4 \frac{1}{3}-5 \frac{1}{4}$ in the length, length of head $4-4 \frac{1}{2}$. Breadth of head $1 \frac{2}{5}-1 \frac{4}{5}$ in its length, diameter of eye $4-6$, length of snout $3 \frac{1}{3}-4$, interorbital width $2 \frac{3}{5}-3 \frac{1}{5}$. Snout obtuse; anterior edge of upper jaw slightly below the level of the lower margin of the eye; maxillary extending to below anterior edge of eye; lower jaw shorter than the upper, with a nearly straight transverse anterior edge. Dorsal III 8-9, its origin a little nearer to tip of snout than to base of caudal ; third simple ray slender, articulated, not serrated. Anal III 50-7. Pectoral extending $\frac{1}{2}-\frac{8}{5}$ of the distance from its base to the base of ventral. Origin of ventral below or a little behind the middle of dorsal. Caudal forked. Caudal peduncle $2 \frac{1}{3}-2_{4}^{3}$
as long as deep. Greyish above, silvery below; upper part of body with irregular dark spots.

Ten specimens, $110-250 \mathrm{~mm}$. in total length.

## 2. Schizothorax dipogon.

Depth of body about $5 \frac{1}{2}$ in the length, length of head $4 \frac{1}{2}$. Upper profile of head nearly horizontal to just in front of the nostrils, where it bends abruptly downwards and becomes nearly vertical. Breadth of head $1 \frac{3}{4}$ in its length. Snout obtuse, much shorter than postorbital part of head. Diameter of eye 6 in the length of head, interorbital width $3 \frac{1}{4}$. Mouth subterminal ; lower jaw apparently without horny covering ; lips strongly developed, continuous, the upper with median prolongation, the lower notched medianly. No anterior barbel; posterior barbel $1 \frac{1}{3}$ the diameter of eye. Scales regularly arranged anteriorly above the lateral line, becoming smaller and irregular on the lower part of the side in the abdominal region ; lower part of thorax and abdomen naked ; about 90 scales in a longitudinal series. Dorsal III 8 , the third simple ray slender, articulated, not serrated; origin of dorsal far in advance of the bases of the ventrals, nearer to tip of snout than to base of caudal. Anal III 6. Pectoral extending a little more than $\frac{1}{2}$ the distance from its base to the base of ventral ; ventral extending $\frac{2}{3}$ of the distance from its base to the origin of anal. Caudal forked. Caudal peduncle $2 \frac{2}{3}$ as long as deep. Brownish above, lighter below; dank spots on the upper surface of the head and one on each scale of the upper part of the body.

A single specimen, 265 mm . in total length.
In the peculiar shape of the head, the structure of the lips, and in having the third simple ray of the dorsal slender and articulated this species resembles S. Regelii, Herz., but differs notably in the absence of the anterior barbels and in having the thorax and abdomen naked.

## 3. Schizothorax Waltoni.

Depth of body $4 \frac{1}{3}$ in the length, length of head 4 . Upper profile of head descending slightly to above the nostrils and thence more strongly to the tip of snout. Breadth of head twice in its length. Snout pointed, a little shorter than postorbital part of head. Diameter of eye $6 \frac{1}{4}$ in the length of head, interorbital width $3 \frac{2}{3}$. Mouth subterminal ; lower jaw apparently without homy covering; upper lip slighty elevated medianly; lower lip with a small median lobe and a pair of well-developed lateral lobes; 2 barbels on each side,
subequal, nearly $\frac{1}{4}$ the length of head. Scales regularly arranged, 124 in a longitudinal series; thorax and abdomen scaly. Dorsal III 8, the third simple ray a stout coarsely serrated spine, $\frac{2}{3}$ the length of head; origin of dorsal behind the bases of the ventrals, nearer to base of caudal than to tip of snout. Anal II 5. Pectoral extending less than $\frac{2}{3}$ the distance from its base to base of ventral ; ventral extending nearly to the vent. Caudal forked. Caudal peduncle $1 \frac{1}{3}$ as long as deep. Olivaceous; fins pale.

A single specimen, 160 mm . in total length.
This species is allied to S. progastus, MacClell.

## 4. Schizothorax macropogon.

Depth of body about 4 in the length, length of head $4!$. Upper profile of head straight, oblique. Breadth of head $1 \frac{1}{3}$ in its length. Snout rounded, shorter than postorbital part of head. Diameter of eye $5 \frac{1}{3}$ in the length of head, interorbital width $2 \frac{2}{3}$. Mouth iuferior; lower jaw without horny covering ; fold of the lower lip broadly interrupted ; 2 barbels on each side, subequal, $\frac{1}{2}$ as long as the head or more. Scales small and irregularly arranged on the anterior part of the body, about 160 in a longitudinal series; lower part of thorax and abdomen naked, except for some rudimentary imbedded scales. Dorsal III 8, the third simple ray a stout coarsely serrated spine, about $\frac{3}{4}$ the length of head; origin of dorsal behind the bases of the ventrals, nearer to base of caudal than to tip of snout. Anal III 5. Pectoral extending $\frac{3}{4}$ of the distance from its base to the base of ventral ; ventrals extending nearly to the vent. Caudal forked. Caudal peduncle $1 \frac{3}{4}$ as long as deep. Dark greyish, with some darker spots on the upper part of the body; fins dusky.

A single specimen, 230 mm . in total length.
Distinguished from allied species by the long barbels.

## 5. Nemachilus tibetanus.

Depth of body 5 in the length, length of head 4. Snout a little shorter than postorbital part of head, 14 as long as eye, the diameter of which is 5 in the length of head and $1 \frac{1}{2}$ in the interorbital width. Breadth of head 15 in its length and equal to its depth. Cleft of mouth extending to below the nostrils; lips moderately thick, plicated, the lower interrupted medianly ; barbels six ; outer rostral barbel reaching the base of the maxillary barbel, which is a little shorter than the eye. Scales entirely wanting. Dorsal II 8 , its origin equidistant from anterior margin of eye and base of caudal.

Anal II 6. Pectoral extending $\frac{8}{5}$ of the distance from it base to the base of ventrals. Ventrals 9 -rayed, extending to the origin of anal. Caudal emarginate. Caudal peduncle slender, $3 \frac{1}{2}$ as long as deep, its length $\frac{3}{4}$ the length of head. Greyish, with irregular dark spots on head, body, and fins.

A single specimen, 125 mm . in total length.
Allied to $N$. Tadacensis, Günth.
XV.-Description of a new Butraclian of the Gemus Bombinator from Yuman. By (f. A. Boulevger, F'.R.S.

## [Plate XIII.]

Only three species of Bombinator were previously known13. i!neus, Laur., and 13. puchippus, Bp., from Europe, and 13. orientalis, Blgr., from Manchuria, Corea, and Northern China. To my great surprise and gratification a small series of Batrachians collected by Mr. John Graham near Tong Chuan Fu in Yunnan (altitude about 6000 feet), which has just reached the British Museum, contained three examples of a fourth species, remarkable for its large size and as greatly extending the known range of this genus and also of the small family, Discoglossidæ, to which it belongs. For this new species I propose the name

## Bombinator maximus. (Pl. XIII.)

Vomerine teeth in two small groups or short transverse series close together behind the level of the choana. Tongue large, circular, scarcely free at the sides and behind. Head broader than long; snout rounded, not quite as long as the diameter of the orbit; no canthns rostralis; nostril equally distant from the eye and the tip of the snout ; interorbital space narrower than the upper eyelid, nearly equal to the distance between the nostrils. Fingers short, obtusely pointed, first shortest, third longest, fourth a little longer than second; no subarticular tubercles ; two round palmar tubercles, inner larger and more prominent. Tibio-tarsal articulation reaching. the shoulder, tareo-metatarsal articulation reaching the eye; tibia as long as the femur, the heels meeting when the legs are folded at right angles to the rhachis; foot as long as the tibia; toes short, obtuse, flattened, only half-webbed; no subarticular tubercles; a small, rounded inner metatarsal tubercle. Upper parts covered with small warts intermixed with very large glands studded with pores, similar to the parotoids of toads; the largest are situated behind the eyes (true parotoids), on the tibia, on the tarsus, and on the back, where they form a pair of curved or angular chains behind the head, with
the convexity turned inwards. Lower parts nearly smooth; a more or less distinct gular fold. No horny spines on any part of the body. Blackisholive above, with rather ill-define l black markings forming vertical bars on the upper lip and cross-bars on the limbs; only the imer finger and toe with a light tip ; a more or less distinct light transverse spot on the back, just behind the head. Lower parts marbled bright

Female, $s$ maller specimen, upper riew of head and anterior part of body, natural size.
orange and black, in about equal proportions, or the black predominating; greater part of palm and sole orange, this colour involving the inner digit; the orange of the lower surface of the arm either extending across the breast, or widely separated from a pair of pectoral spots ; plantar, tarsal, and tibial orange spots continuous or interrupted ; the orange not extending on the back of the thighs.

| From snout to vent | ${ }_{(88}^{1 \mathrm{~m}}$ |
| :---: | :---: |
| Lenyth of head | 19 |
| Width of head. | 2:3 |
| Diameter of eve | 6 |
| Interorbital width | : |
| Fore limb | 3 2- |
| Hind limb | 73 |

| Foot | 24 |

The three specimens here described are females.

## EXPLANATION OF PLATE NIII.

[^29]XVI.-Description of a new Suake of the Genus Atractaspis from Mount Kenya, British East Africa. By G. A. Bollenger, T.R.S.

A smali, collection of reptiles made by MI. S. L. Hinde at Fort Hall, Mrount Kenya, 4400 feet, contains, in addition to specimens of four species previously described by me from East Africa-viz. Lygosoma clethrotis, Chameleon Jacksoni, Chumeleon Roperi, and Glauconia Emini,-an example of the Viperid genus Atractaspis, unique in having two postoculars instead of one. It represents a new species, which I propose to name

## Atractaspis bipostocularis.

Snout very short, rounded. Portion of rostral visible from above half as long as its distance from the frontal; suture between the internasals as long as that between the prefrontals; frontal a little longer than broad, nearly twice as long as its distance from the end of the snout, as long as the parietals; one pra- and two postoculars; a very large temporal wedged in between the fourth and fifth upper labials and in contact with the lower postocular ; five upper labials, third and fourth entering the eye, fourth largest ; first lower labial in contact with its fellow behind the symphysial; four or five lower labials in contact with the chin-shiells, fourth or fitth very large. Scales in 23 rows. Ventrals 233 ; anal divided; subcaudals $2 t$ pairs. Dark olive above and beneath, upper surface of head paler.

Total length 240 mm. ; tail 16 .
A single young specimen.
XVII.-List of a Cellection of Neuroptera Odonata (Dragonflies) formed by G. A. K. Marshall, Esq., at Salisbury, Mashonalend, with Descriptions of a new Genus and I'wo new Species. By W. F. Kirby, F.L.S.S., F.E.S.
Thins small collection was recently presented to the Natural History Muscum by Mr. Guy Marshall, and is interesting on account of all the specimens being marked with the month of capture. A few notes are also added, chiefly on the colours of the living insects.

## Libellulidæ.-Libellutine.

Pantala flavescens, Fabr: : (no. 29) Nov. 1903.-Four specimens.
Trithemis arteriosa, Burm.: (no. 42) October 1903, April 1904.-Seven specimens.

Trithemis stictica, Burm.: (no. 53) April 190t.-One specimen.
Crocothemis erythrea, Brullé: (no. 25) Oct. 1903, April 1904.-Hive specimens.

Orthetrum chrysostigma, Burm.: (no. 14) April 1904.Three specimens.
Misthotus Marshalli, sp. n. (vide infra) : (nos. 6 \& 2b, immature) Oct. 1903, (no. 5, adult) Nov. and Dec. 1903.Five specimens.
Diplacodes exul, Selys: (nos. 3 \& 26) Oct. 1903, (no. 40) Nov. 1903, (no. 11) March 1904.-Four specimens.

## Æschnidæ.——tschnine.

Ilemianax ephippiger, Burm.: (no. 30) Nov. 1903.-Two specimens.

## Agrionidæ.-Cenagrioninee.

Disparoneura glauca, Burm.: (no. 23) November 1903.One specimen.
Micronympha senegalensis, Ramb.: (nos. 46 \& $4 x$ ) Oct. and Nov. 1903, (no. 46, November). "Sides of thorax and of two basal and two apical segments of abdomen bright blue." ( $G$. M.)—Several specimens.

Pseudagrion punctum, Ramb.: (no. 41) Oct. and Nov. 1903, "Apex of abdomen pale blue." ( G. N. M.) ; (no. 45$)$ Nov. $^{5}$ 1903, "q of 24. " (G. M.) - Nine specimens.
Pseudagrion Deckeni, Gerst. (according to the above note $=P$. punctum, $\delta$ ) : (nos. 24, 41, 43, 44) Oct. and Nov. 1803, (nos. $44 \& 46$ ) April 190t.-Fourteen specimens.
Agriocnemis exilis, Sclys: (no. 16) Oct. 1903.-One specimen.
Lestes obscurus, Kirb.: (no. 15) Oct. 1903, March and April 1904.-Four specimens.

## Genus Misthotus, nov.

Eyes contiguous, scarcely expanded behind, frontal tuberele rounded; abdomen about as long as the fore wings, rather slender, neither thickened nor constricted at the base, with the second and third segments carinated; terminal appendages of male rather short and slender, thickened towards the extremity, scarcely longer than the broad triangular lower appendage: fore wings with 11 or 12 continuous antenodal cross-nervures and 9 to 11 postnodal cross-nervures in the upper space and 7 or 8 in the lower (only 5 in female) ; pterostigma rather long, with 2 or 3 nervures in the space below it ; only 1 nervure in the lower basal cell; no supratriangular nervures; triangle regular, traversed, followed by 3 rows of post-triangular cells, only increasing towards the extremity, subtriangular space consisting of 3 cells ; sectors of the arculus stalked, only slightly waved, lower sector of the triangle rising just beneath the triangle: hind wings with 9 or 10 continuous antenodal cross-nervures (sometimes an accessory one in the upper series), and 11 postnodal upper cross-nervures and 8 lower; triangle untraversed, followed by two rows of cells increasing above the upper sector, which rises close to the lower one.

Differs from Orthetrum chiefly by the uninflated and unconstricted abdomen. Several species descibed under (),thetrum (among others O. flavidulum, Kirb.) will probably fall into this genus.

## Misthotus Marshalli, sp. n.

Exp. al. $58 \mathrm{~mm} . ;$ long. pter. 3 mm . ; long. corp. 34 mm .
Male.-Head black; vertex purple, coarsely punctured; below it a yellow spot on each side, touching the eye; mentum with the sides broadly yellow; onter orbits yellow, spotted with black ; thorax and abdomen pruinose blue, with some slight yellow markings at the base of the legs, on the sides of the base of the abdomen beneath, and on the lower abdominal appendage above; thorax very hairy; legs black: wings very clear lyyaline, with blackish neuration; stigma dark brown, slightly bordered with smoky yellow on the imer edge; base of wings with a smoky yellow patch, nearly obsolete on the fore wings; membranule of hind wings small, grey.

Salisbury, Nov. and Dec. 1903. Two specimens.
Female (taken in cop. with one of the two males described
above, in Nov. 1903) and immature male (Ost. 1903). - IHeal yellow, antennal tubercles surrounded with purple (vertex wholly purple in male) ; thorax yellow, a black isosceles triangle above, pointing backwards, and with 5 or 6 more or less confluent oblique stripes on the pleura; interalary space varied with black and yellow ; abdomen yellow, with 3 black bands, widening behind, one median, the others lateral ; the lateral ones more or less interrupted towards the base; fourth segment with a black transverse line near the base, simulating an imperfect carina (in the pruinose males first described this is hidden). All else as in the adult males previously described.

In a still more immature male, taken in October, which seems to belong to the same species, the neuration is reddish, with the yellows at the base of the wings more extended; the dark median triangle of the thorax and the median ab lominal stripe are barely indicated, and the pleura and sides of ablomen at the base are almost white, with oblique black lines.

## Misthotus ambiguus, sp. n.

Exp. al. $70 \mathrm{~mm} . ;$ long. pter. 3 mm. ; long. corp. 38 mm .
Male.-Vertex purple, with greenish shades in certain lights; face mostly greenish; rhinarium black, with an orange spot on each side; mentum black, with a broad orange band on each side; outer orbits yellow, spotted with black. Budy and wings nearly as in the last species; fore wings with 11 continuons cross-nervures, and sometimes an accessory one on one side, not continued beneath, 10 in the upper postnodal space, and 7 in the lower: hind wings with 7 or 8 continuous antenodal cross-nervures, 10 or 11 in the upper postnodal space, and 7 or 8 in the lower.

Otherwise as in the last species.
Hab. Transvaal (H. Ross) ; Cape Colony.
A larger and stouter insect than M. Marshalli. Perhaps allied to Orthetrum farinosum, Förster, also from the Transvaal.

This is not one of Mr. Guy Marshall's captures, but I describe it here as an additional species of the new genus Misthotus.
XVIII. - Notes on the Synonymy of Thecla spurina, Hew., and Thecla ericusa, Hew. By Hamilon II. Druce, F.Z.S., F.E.S.

Mucir confusion has been caused by Hewitson having described the male and female of both these species as distinct, which is the more remarkable as the female only differs on the underside by being paler in colour. Besides the specimens in the National Collection I have examined those in Mr. Godman's collection, amongst which are several co-types of Hewitson's which were formerly in Bates's possession and several of his types.

The first species described by Hewitson is Thecla spurina*, the type of which (a female) is now in the British Museum; it is in indifferent condition and without locality. There are four females in Mr. Godman's collection (two Tapajos and two Pará) marked by Bates "spurina." 'These differ from the type only by being rather darker and by the orange spot between the tails on the upperside being less apparent, this, however, varying slightly in all four specimens. The specimen referred to by Hewitson as being in Bates's collcction, and which is labelled "spurina, Hew., type," is, in fact, T. ericusa, Hew., of which an excellent figure is given (fig. 162).

We possess a single female from Bartica, British Guiana, obtained by Mr. H. S. Parish, which differs from the Amazon specimens only by being rather richer in colour, doubtless due to its being a fresher specimen, and by the total disappearance of the orange spot between the tails on the upper surface.

A few pages later is described T. stagira $\dagger$, with two vars. ( $a$ and $b$ ).

Mr. Godman's collection contains one male from Bates's cabinet labelled "stagiva" from Trapajos; also one female labelled "stagira" from Tapajos which I am quite convinced is T.pion, G. \& S.f, judging from the colour and pattern of the underside, also by the costal margin of the fore wing being much more concave towards its middle than in T. spurina + .

* Thecla spurina, Hew. Ill. Diurn. Lep. p. 102, t. xxxix. figs. 122, 123 (1867).
$\dagger$ Thecla stagira, Hew. Ill. Dium. Lep. p. 113, t. xxxix. figs. 120, 121 (1867).
$\ddagger$ Thecle pion, Godm. \& Salv. Biol. Centr.-Am., Rhop. ii. p. 56, pl. liv. figs. 28-30.

The var. $a$, to which Hewitson originally gave the name erenea, and subsequently sunk under stagira, I do not know, and do not find it in the Hewitson Coll. or the B. M. Coll. According to the figure it has no brown apex and margin on fore wing above.

The var. $b$, mentioned by Hewitson as from Rio, I am also unable to find, but there is a male in Mr. Godman's collection of about the same size from Panama obtained by Mr. Champion.

Again, in the same work Hewitson describes and figures T. volana* from the collection of the late W. W. Saunders.

In Mr. Godman's possession is a single female labelled "S," and on another ticket "Amazon." I have no doubt that this is Hewitson's type; it formerly belonged to Mr. Herbert Druce, who obtained it from the Saunders Collection at its dispersal. It cannot be separated from T. spurina. Messrs. Godman and Salvin, in Biol. Centr.Americana, Rhop. ii. p. 52, refer to this species as T. stegira, probably because no Central-American females were sent to them.

Again, Hewitson describes the female as Thecla timea $\dagger$ from Bates's collection, and the type is now in Mr. Godman's possession. It is slightly smaller than the type T. volana, but I can detect no other difference.

From a perusal of the foregoing remarks it will be seen that the synonymy of this species is as follows:-
Thecla spurina, Hew.
" stagira, "
" volana, "
" timera, "
" stagira, " Godm. \& Salv.
T. spurina, like many other Theclas of which any considerable number of specimens can be got together, proves to have a rather wide range. I have examined specimens from Chiriqui and Panama in (Ventral America, males only, and both sexes from British Guiana; from Manaure, N. Granada; from Tapajos and Pará, on the Amazon; from Paraguay (captured by Perrens) and from Brazil (Chapada), sent by Mr. H. H. Smith.

[^30]The next species here dealt with is Theclu ericusa*, described by Hewitson from a female Brazilian specimen in the collection of the late W. W. Saunders. I have been unable to trace this type, but the figure is an excellent one, and there should be no difficulty in identifying it. Shortly afterwards Hewitson describes the male under the name Thecla voconia $\dagger$ from an unknown locality. This type is now in the British Museum, and without doubt $=T$. ericasa.

There are specimens from Venezuela (one female) and Rio (one male) in Mr. Godman's possession which were formerly in the Kaden Collection, and one female from Minas Geraes (Bates), also two males and two females from Chapeda, Brazil, obtained by Mr. H. H. Smith, and two males from Paraguay (Perrens).
T. ericusa, which varies much in size, is at once distingruished in the male from T. spurina by possessing a simple brand on the fore wing place l just beyond the en 1 of the cell, whilst that species has a double brand partly placed in the cell and partly beyond. The possession of this simple brand probably points to its near alliance with Thecle brescia $\ddagger$, a well-known Central-American species.
XIX.-On Two new Lencanix from British New Guinea. By George 'I. Bethune-Baker, F.L.S., F.L.S.

## Leucania leucosphenia, sp. n.

o. Head and collar ochreous brown, patagiæ and thoras reddish ochreous; abdomen pale ochreous brown, with a large pale yellowish anal tuft; legs pale ochreous brown, with dark reddish femora. Primaries pale ochreous brown, with all the veins palely outlined and a pale dash at the lower angle of the cell ; cell filled in with pale reddish, with a like-coloured basal dash on its lower margin; a pale patch below the centre of the cell; a double postmedial row of dark dots; a greyish wedge-shaped mark on the termen below the apex; termen darkly dotted, immer margin pale,

[^31]with a dark dash above it near the base: secondaries pinkish brown, paler towards the base.
\%. Like the male in all respects.
Expanse, os 44 , +46 mm .
The types from Dinawa are in my collection; the species flies in August.

## Leucania cryptargyria, sp.n.

ठ. Head pale rufous brown ; collar pale purplish brown, with four dark lines horizontally across ; patagiæ reddish brown, tinged with grey; abdomen pale ochreous brown ; palpi pale purplish brown, pale ochreous internally; legs pale ochreous brown, striped with reddish; spines black at the base; mid leg; with tibia fringed with long pale hair ; an abdominal tuft of longish black hair at the base. Primaries pale ochreous brown, tinged with reddish in the cell and up to the apex, to which point the darker area tapers gradually; costa broadly whitish grey; a double postmedial row of black points; termen slightly clouded; the veins are more or less irrorated with black scales and the inner marginal area has a patch of similar-coloured scales: secondaries warm brown, slightly pinkish, with the costa and inner margin paler. Fringes pale pinkish, outer half white. Under surface: both wings uniform lustrous metallic silver, with a blackish spot on the costa a third from the apex.

Expanse 48 mm .
The type is in my collection from Dinawa.

> XX.-On a new Vole from Kashmir. By J. Lewis Bonhote, M.A.

The collection of voles sent home from Kashmir by Col. A. E. Ward contains three specimens of a most interesting new species allied to Microtus nivalis, for which I propose the name

## Microtus imitator, sp. n.

Differs externally from $M$. nivalis only in its smaller size and slightly browner coloration.

General colour above grizzled greyish brown, each hair being dark at its base, with a light subterminal portion and a

Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.
black lip; interspersed among these are longer pure black hairs. The colour is deepest across the back and paler on the flanks and checks. Underparts whitish, tinged with yelluw; hairs with dark bases. Feet greyish. 'Tail long and bicolor, brown above, white below. Ears moderate, rounded, and clothed with short hairs similar in colour to the upper parts.

The skull is slightly smaller and flatter than in true nivalis, but the brain-case is rather more rounded at the sides. The auditory bulle smaller, less elongate, and well rounded, thus slightly compressing the basioccipital.

Teeth generally resembling those of M. nivalis, with two important exceptions. In the species under consideration the spaces are rather narrower and smaller than in nivalis, the third molar of the upper jaw has four external angles instead of three, and the pusterior lobe of the same tooth has a slight constriction on its imner edge, tending to form a fourth interior angle. In the lower jaw the anterior arrowshaped head of the first molar is not symmetrical, but is elongated on its external side to form an oblong rounded space; a tendency towards this shape is found, so Dr. Forsyth Major tells me, ma specimen of nivalis from Moment Ilermon, but
is never found among the western forms. The anterior external space of the third lower molar is similarly modified.

Dimensions. Head and body 105 mm . ; tail 45 ; hind foot 15 ; ear 12.

Skull. Length of palate 12 mm .; length of nasals 8 ; length of molar series 6 ; width of brain-case above posterior roots of zygomata 13.

Hab. 'Tullian, Kashmir. Alt. 11,000 feet.
Type. B.M. 5. 1. 5. 12. of ad. Tullian, Kashmir. Colleeted by Col. A. E. Ward, 14 th July, 1903.

In outward appearance, as well as in skull-characters, this vole is undoubtedly allied to M. nivalis of Europe, which, however, has not hitherto been found east of the Caucasus; so that its discovery in Kashmir forms a considerable eastward extension of this group. Its smaller size, slightly browner coloration, and dental characters enable it to be distinguished easily from the typical nivalis.

## XXI.-A new Ficalbia from West Africa. By F. V. Theobald, M.A.

## Ficalbia nigripes, sp. n.

IIead black. Thorax pale bright yellowish brown, with two parallel dark lines behind. Abdomen deep brown, with narrow pale basal bands. Legs, antenne, palpi, and proboscis deep blackish brown. Wings with pale scaled veins and with deep brown costa.
$\delta^{2}$. Head clothed with flat deep black scales and black upright forked scales. Antennæ deep blackish brown, with paler dusky bands and deep brown plume-hairs. Proboscis deep blackish brown, swollen apically; palpi small, deep brown.

Thorax pale brown, clothed with long, narrow, curved, pale, dull yellowish scales, except for two parallel bare lines, and with two broad lines of long, nariow, curved, black scales on each side of the bare space in front of the scutellum and extending past it ; two rows of long black bristles and numerous black ones over the roots of the wings; scutellum clothed with flat black scales and with brown border-bristles; metanotum deep brown; pleura pale ochreous.

Abdomen deep blackish brown, with white basal bands and brown lateral hairs.

Legs deep blackish brown ; the coxa pale ochreous.
Wings with brown scales; fork-cells short, of nearly equal length; base of the first submarginal cell nearer the apex of the wing than that of the second posterior, its stem about one and a half times the length of the cell; stem of the second posterior not quite one and a half times the length of the cell; posterior cross-vein sloping lackwards, not quite its own length distant from the mid vein; median vein-scales in single line; lateral vein-scales large and bluntly lanceolate, existing on the scond, third, and branches of the fourth veins only, narrower ones on part of the first long vein, those on the first and sulcostal short and spatulate, like those forming the median vein-scales, only in two rows ; costa with an inner row of short spatulate scales, and the outer border with deep brown spiny ones; the sixth vein is much curved apically.

Length 2.8 mm .
Time of appearance. December.
Hab. Kortright, Freetown, Sierra Leone, 1200 feet (Major F. Smith, II.S.(., R.A.M.C.).

Obs. Described from a perfect male. The specimen was bred by Major Smith from a larva taken in a hole in a brook.

This is the first Ficalbia that has occurred in Africa. The only other species with banded abdomen is F. mimime, Theob., from South India, but the Indian species has banded legs.
XXII. - American Hymenoptera: new Bees and a new Proctotrypid. By 'T. D. A. Cockerell, University of Colorado.

Prosopis crenulata, sp. n.
む.-Length about 5 mm .
13lack; head large, abdomen slender ; labrum, greater part of mandibles, scape in front, and face below middle lemonyellow; supraclypeal mark quadrate, a little higher than liroad, slightly emarginate above; lateral face-marks filling the space between the clypeus and supraclypeal mark and the eye, truncate and minutely crenulate above; the yellow thus ends abruptly at about the same level right across the face, though its upper margin is not straight, but concave; flagellum brown beneath; front and vertex strongly punctured; mesothorax well punctured; metathorax polished and shining, with a very narrow basal sculptured area; thorax
entirely black; tegula piceous; wings strongly dusky; femora black, except more or less at apex, tibiae and tarsi yellow, the small joints of the tarsi infuscated; abdomen black, closely and distinctly punctured.

Hab. Mexico ; further particulars unknown (Baker collection, no. 1785) \%.

The black scutellum distinguishes it from most of the Mexican species; I do not know of any close ally. In my table in ' Entomologist,' Aug. 1898, it runs to P'. rugosulu, Clll., but_it is quite distinct from that.

## Celioxys angelica, sp.n.

ㅇ. - Length about $9 \frac{1}{2} \mathrm{~mm}$.
Entirely black, including the legs; pubescence white; tegula dark brown; wings with the apical half dusky; scutellum with the lateral teeth slender and somewhat hooked, no median tooth or tubercle; concavity of first abdominal segment bounded by a distinct rim, behind which is a narrow white hair-band; segments 1 to 5 with narrow apical hair-bands; transverse grooves on segments 2 and 3 broadly interrupted in the middle; apical dursal segment rather broad, pointed (the point not at all upturned), not notched, but rather suddenly depressed about the middle, the depressed apical part with erect hairs; last ventral segment surpassing the dorsal, broad, with the margin ciliated with dark bristles, the apex not notched, but having a minute tooth-like prominence; penultimate ventral segment with strong punctures, and no little ones between.

Mab. Los Angeles, California (Dr. A. Duvidson).
Allied to C.modesta, Smith, and C. gilensis, Ckkll., but easily known from these by the last dorsal segment having no upturned point. From C. apacheorum, Ckll., it is known by its smaller size, apical ventral plate with a little projection, and penultimate ventral segment without little punctures interspersed among the large ones.

## Triepeolus wyomingensis, sp. n.

## ठ. -Length just over 11 mm .

black, including the antenna, legs, and their spurs; pubescence greyish creamy, pure white on face; clypeus
\% Mr.!E. S. G. Titus, who has access to Mr. Baker's note-boulk, informs me that no. 1785 , the number attached to the tipe of Prosphis crenulutw, signifies that it was collected by H. H. II yde in the autumn of la 05 , hy "sweeping \&c.," at Medellin, State of Vera Cru\%, Mexico.
minutely rugnse, with scattered large punctures; tegule exceedingly dank brown: wings hyaline, with only a faint brownish tint; nervures dark reddish brown, paler basally; marginal and third submarginal cells each with a short appendicular nervure; third submarginal cell longer on marginal than on third discoidal; second submarginal cell considerably narrowed above, receiving the first recurrent nervure at its middle; basal nervure going a considerable distance basad of transverso-medial: mesothorax minutely roughened, with a broad but thinly hairy band across the anterior part, sending two tongues backwards; scutellum strongly bilubed, the lateral teeth short, black; pleura densely punctured, with a large circular bare patch: abdomen 6 -banded, the first segment covered with hair, except the usual median patch, which is pointed but not greatly prolonged laterally; second segment with the lateral upward extensions of the band forming right angles, as in T. nigriceps (Smith); venter with pale hair-bands on the second and third segments and a coarse curled purplish-sooty fringe on the fourth.

Hab. Wyoming; no other particulars known. Received from Mr. John H. Lovell.

Superficially like T. concolor (Rob.), but the markings are not so yellow, and the patterns of the mesothorax and first abdominal segment are quite different; the face also is broader below, with the hair white (pale golden in concolor), and the sides of the vertex are densely punctured and dull, without any shining surface showing between the punctures, as it does in concolor. From T. donatus (Smith), which it rather approaches in the colour of its markings, it differs at once in the pattern of the thorax and abdomen. From T. nigriceps (Smith), which it approaches closely in pattern, it differs by its smaller size and wings not at all violaceous.

## Triepeolus callopus, sp. n.

ㅇ. -Length 10 mm . or slightly less.
Black, with the usual markings of pale ochraceous pubescence; legs bright ferruginous; basal three fifths of mandibles, labrum, and anterior margin of clypeus bright ferruginous; clypeus minutely roughened, with scarcely indicated scattered punctures; a prominent keel between the antennæ; scape dark; flagellum ferruginous, but much blackened, especially above, the first joint and base of second brighter; mesothorax nude, except for two stripes of pubescence on the anterior part and a patch at each posterior
lateral corner, its anterior margin quite bare, contrasting with the adjacent prothorax, which is very pubescent; scutellum with the anterior half bure and the posterion halt pubescent, rather prominent, slightly bilobed, with the lateral tecth black, and very short; metathorax pubescent; pleura rather coarsely rugoso-punctate, pubescent, with a very large round bare area ; tegula aprico-colour, with hyaline margins; wings clear, second submarginal cell triangular ; tibial spurs' black: abdomen with entire bands on the hind margins of the first four segments; first segment with the basal half wholly covered with pubescence, and the black area a broad transverse band, rounded at the ends; second segment with the apical band sending from each side a broad process antero-mesad, forming an acute angle with the band; apex red, dorsally with a broad-oval flattened area; last ventral plate curved strongly downwards at the end; first three ventral segments with much pubescence, the last two bare, the penultimate one black margined with red.

IIab. Redondo, California (Dr. A. Davidson).
By the marking of the first abdominal segment this resembles T'. occidentalis (Cresson) ; by the structure of the apex of the abdomen it resembles T. penicilliferus (Brues) and T. concavus (Cresson). It is a much smaller insect than either of the last-mentioned.

## Synkalonia Gillettei, sp. n.

$\delta^{2}$.-Length about 16 mm . ; antenne slightly over 11 mm .
Black, with rather dull white pubescence, faintly tinged with yellowish on the thorax; antenne entirely black, apical portion crenulated, third joint hardly over a quarter length of fourth, fourth longer than fifth; clypeus and labrum lemon-yellow, clypeus coarsely rugoso-punctate; mandibles black, with an obscure pale mark on basal portion; thorax densely hairy; tegule ferruginous, with hyaline margins; wings slightly dusky, nervures dark ferruginous, basal nervure meeting transverso-medial; legs black, small joints of tarsi ferruginous, spurs pale reddish; hair of legs all pale, that on inner side of basal joints of tarsi ferruginous; abdomen hairy, segments 3 to 6 with white pruinose or velvety bands, such as usually seen in females of Symhalonia; venter with short scanty dark brown pubeseence, except at sides, where it is white and conspicuous.

Hab. Fort Collins, Colorado, June 12, 1902 (Colorado Experiment Station).

Nearest to S. frater (Cresson), but considerably larger,
with the abdomen more hairy and distinctly banded. It has a strong superficial resemblance to Melissodes macherantherce, Ckll., but the antenne are much longer than in that species.

## Synhalonia fulvitarsis (Cresson).

Fort Collins, Colorado, May 27, 1900 (Colorado Experiment Station). Described from "Colorado," but this is the first indication of a precise lucality or the time of flight.

## Proctotrypidæ.

Proctotrypes coloradicus, sp. n.
ㅇ.--Length 9 mm . or slightly over, with the cauda exceeding 10 mm .

Entirely bright ferruginous, only the eyes black, and the antemne infuscated towards the end; head quadrate, but broader than long; first joint of flagellum longer than second ; metathorax cancellate, with a fine median, longitudinal, raised line; second abdominal segment with only faint strie at the extreme base; cauda somewhat less than half length of abdomen: upper wings dusky, marginal cell extremely minute, first (and only) submarginal cell extremely large; first discoidal open on outer side, the cubital nervure (which is very faint) not at all directed upwards, as it is in Ashmead's figure of $P$. caudatus (which also has the first discoidal closed); stigma not so near apex of wing as Ashmead figures for caudatus.

Ilab. Boulder, Colorado, about 100 yards from no. 930 14 th St., Oct. 1, 1904, ruming on the ground, looking like an ant (Cocherell).

Easily known by its large size, bright red colour, and the venation. It is most nearly allied to P. xallidus, Say.

> Boulder, Colorado, U.S.A.,

December 1904.

## XXIII.-Three undescribed Coleop,tera from Natal. By W. L. Distant.

Among some insects recently sent to me by Mr. H. W. Bell-Marley from Natal were a certain number of the smaller Longicorn beetles, some of which were described species which camot at present be included in my enumeration of
the Longicomia of the Transvaal, though they may probally occur in that country, while three appear to be new species, one necessitating the proposal of a new genus. F'or the systematic position of that genus I am again indebted to the advice of my friend Mr. C. J. Gahan.

## Order COLEOPTERA.

## Fam. Cerambycidæ.

Subfam. Layinne.
Division Acmoceridaria.
Tambusa, gen. nov.
Head considerably depressed between the antemniferous tubercles, which are prominent and inwardly and outwardly angulate; front oblique, with a small spinous callosity on each side near base; eyes coarsely facetted, the lower lobes large ; antennæ a little longer than the body, thickly pilose, finely hirsute beneath ; first joint somewhat transversely incrassate, its margins tuberculate, third and fourth longest and subequal in length, but third a little incrassate, fifth slightly longer than any of the remaining joints, which are subequal in length; pronotum about as long as broad, discally gibbous and laterally oblique, with a prominent spine near each posterior angle, two central, posterior, elevated, laminate processes, with their apices shortly tuberculonsly spinose, and with a short central spine between them; elytra a little narrowing posteriorly, their apices somewhat obliquely truncate, with a broad, cordate, raised, but inwardly concave process at base ; acetabula of front coxa angulate outwardly; intercoxal process of prostemum triangular; femora thickened, a little compressed at apex and much more so at base; tibiæ very slightly longer than the femora ; first joint of tarsi considerably shorter than the second and third joints together.
'This genus is allied to Idactus, Pasc.

## Tambusa Marleyi, sp. n.

Fulvous brown, with some scattered fuscous mottlings; pronotum (excluding the discal processes) thickly, shortly, palely pilose, the suface very uneven, the outer margins and apices of the discal processes, the apex of the intermediate spine, and the apex of the posterior angles piceous; elytra tomentose, finely tuberculate, the tubercles (excluding those on basal process) arranged in longitudinal series, the basal
process dark fulvous, piceous towards apex, and its posterior margin very palely flavescent; there is a short, curved, immer apical fascia to each elytron, preceded by a transverse much waved line, and an irregular transverse discal spot before

Tambusa Marleyi, Dist.
middle (not reaching margins), pale ochraceous; antenna with the bases of the fifth and succeeding joints greyish; legs (especially the tibire and tarsi) distinctly pilose, at base and apex of tibix greyish, femora and tibix with small scattered piceous spots.

Var.-Posterior margins of the lateral angles and the posterior margin to pronotum and hameral angles and basal process to elytra piceous.

Long. 13-15 mm.
Ilab. Natal: Durban (Bell-Marley).

## Division Nipifonidaria.

## Soridus griseus, sp. n.

Griseous, punctured or minutely spotted with fuscous; head with the basal area from posterior margins of antenniferous tubercles fuscous, punctate, remaining portion and front griseous, the last with the apical area and a transverse fascia from between eyes fuscous; antemme fuscous, shortly
griseously pilose; pronotum fuscously punctate, the disk confluently punctate, with a basal central griseous line; elytra finely pilose, longitudinally irregularly carinate, fuscously punctate, somewhat confluently so on lateral and

Soridus griseus, Dist.
basal areas, their apices subacuminate; sternum and legs fuscously punctate ; abdomen beneath palely griseous, thickly tomentose, obscurely finely fuscously punctate.

Long. $11 \frac{1}{2} \mathrm{~mm}$.
Hab. Natal: Durban (Bell-Marley).
This species only differs from Gahan's genus Soridus in having the apices of the elytra subacuminate, not " broadly subtruncate."

## Division Acanthocinidaria.

Exocentrus polymitus, sp. n.
Pale griseous, much mottled or shaded with bright dark fuscous; head and pronotum sometimes almost entirely fuscous, with the posterior angles griseous, or the surface only fuscously punctate; elytra with two spots (the uppermost largest) on each side of suture before middle, followed by two very irregular and angularly waved transverse fasciæ, humeral angles and a marginal spot before middle dark bright fuscous brown; antenne brownish ochraccous, first joint (excluding base), apices of joints $3-5$, and nearly the whole
of the remaining joints fuscous brown; legs and body beneath fuscous brown; abdomen sometimes with a narrow, central, griscous fascia; pronotum with a strong posteriorly directed

Exocentrus polymitus, Dist.
lateral spine; elytra thickly and finely punctate; antenna about twice the length of body.

Long. 4 mm .
1lab. Natal: Durban (Bell-1Larley).

> XXIV.- A new Lizard and a new Frog, from Borneo. By R. Sifelford, M.A., F.L.S.

## Lygosoma (Kencuxia) Tyneri, sp.n.

Habit lacertiform ; the distance between the end of the snout and the fore limb is contained once and a third in the distance between axilla and groin. Snout moderate, obtusely pointed, somewhat depressed. Lower eyelid scaly. Nostril pierced in a single nasal; supranasals present, but not in contact with each other. Fronto-nasal as broad as long, in contact with the rostral but not with the frontal; the latter as long as the fronto-parictals and parietals together, in contact with the first and second supraoculars ; five supraoculars, the fifth very small, the second the largest ; eight supraciliaries, the first and sccond largest. Fronto-parietals
and interparietal distinct, the latter rather larger than the former and almost entirely separating the parietals; a pair of nuchals; four labials anterior to the subocular. Earopening small. 22 scales round the body; all the scales are smooth; the dorsals are larger than the ventrals. Præanals slightly enlarged. The adpressed limbs overlap. Digits slender, with sharp claws, the basal phalanges cyclotetragonal, the distal strongly compressel; subdigital lamellæ smooth, 20 under the fourth toe. Tail equal in length to head and body. Head greyish olive, some of the scales edged with black; a series of four dorsal scales are black, each scale with a central quadrate olive-grey spot, forming four longitudinal stripes; a dorso-lateral series of scales is olive-grey; sides of neck and body and the limbs covered with brown seales, black-edged; tail greyish olive; ventral surface pale green.

| Total lenoth | $111 m$. |
| :---: | :---: |
| Head. | $1 . t$ |
| Width of head | 10 |
| Body. | 52 |
| Fore limb | 19 |
| Hind limb | 24 |
| 'Tail | 66 |

Hab. Mount Balineau, Muka district, Sarawak.
The type and only known specimen of this species, which has been named in honour of His Highness the Raja Muda of Sarawak, is deposited in the Sarawak Museum. Structurally this skink is very like the other species of the section Keneuxia, but it differs from L. smaragdinum, Less., by the absence of an enlarged scale on the heel, from $L$. olivaceum, Gray, and L. vittutum, Edel., by the smooth dorsal scales.

## Rana sariba, sp. n .

Vomerine tecth in two oblique series commencing from the inner posterior angles of the choanæ. Head broad, snout rounded; interorbital space broader than the upper eyelid; tympanum distinct, about one half the size of the eye. Fingers moderate, the first not extending beyond the second, but shorter than it; the tips of the fingers expanded into small disks about two thirds the size of the tympanum; toes half-webbed, their tips expanded into disks which are a little larger than the disks of the tingers; subarticular tubercles well developed; inner metatarsal tubercle prominent, oval ; no outer tubercle. The hind limb being carried forwards along the borly, the tibio-tarsal articulation just falls short of
the tip of the snout. Skin of the throat and sides of the body with minute tubercles. Reddish brown above, closely marbled with darker brown, tibie with three dark cross-bars ; pale beneath.

From snout to vent 35 mm .
Mab. Mount Saribaw, Samarahan River, Saratwak.
This rather obscure little frog in general appearance resembles small specimens of Rana Kuhlii, D. \& B., but the distinct tympanum and expanded tips of the digits readily serve to distinguish it from that species. The type and only known specimen (a female) is deposited in the Sarawak Museum.
XXV.-The Heterogenetic Origin of Fungus-germs and Morads. By H. Charlton Bastian, M.A., M.D., F.R.S., F.L.S.

> [Plates XIV. \& XV.]

Since my communication to 'Nature' on this subject, on Nov. 24 of last year, I have been devoting much of my leisure time to further observations on the development and transformations of small Zoogloea masses, with the result that I have abundantly confirmed the truth of my original observations, and have also been able to fill up several gaps in my previous knowledge. I have satisfied myself also that by far the best way for readily investigating these phenomena is to obtain very thin bacterial scums, by using filtered infusions not too strong, and a depth of fluid of rather less than one inch. As all the processes that I have been describing. go on in the dark quite as well as in the light, the simplest plan is to filter the infusion, prepared as previously directed *, into small one-ounce earthenware pots, over which the cover's are then placed till the time comes for the examination of their contents. If three or four pots are prepared at the same time, they may be opened at will on successive days, or some may be exposed to one temperature and some to another.

It is important to bear in mind two fairly distinct aspects of my observations, corresponding with different stages in the processes described. We have to do (1) with the growth, the individualization, and the processes of segmentation taking place in masses of Zoogloea. We have also to do (2) with * 'Nature,' Nor. 24, 1904, p. 77.
the question of the ultimate destination, or the transformation, of the products of such segmentation. These are two parts of the subject that are to some extent distinct, and which are well worthy of further separate consideration.
(1) The Developmental Tendencies in Zooglox.-If it be asked, what amount of knowledge do bacteriologists possess, on this subject? the answer must be "next to nothing," if we are to judge from the extreme paucity of informatio: on the subject which is to be found in any of their text-books. Yet if they would only deign to look at what takes place in a filtered hay-infusion, they could very soon satisfy themselves that Zoogloa masses not only grow rapidly, but undergo definite developmental processes, associated with marked molecular changes, as evidenced by their different behaviour at different stages to logwood or other stains, as well as by the results of microscopical examination. And while these molecular changes are taking place the masses may segment into larger or smaller portions and often into minute spherical or ovoid units, showing that an organizing process is taking place.

If we look at the constitution of Zoogloea masses as shown in fig. 1, A and B (Pl. XIV.), it may be seen that we have only to do with bacteria imbedded in a varying proportion of gloeal material. But later on, when the mass has grown, and some amount of segmentation has taken place, as in C , it may often be seen that we have still only to do with aggregates of bacteria. At other times, it is true, the molecular changes that have taken place in the mass have so altered its constitution (making the segments very refractive) that the included bacteria are no longer recognizable, as in the paler segments shown in D , which soon become resolved ints the dark brown Fungus-germs seen by their side.

But now an important link in the proof of my views may be brought forward. The Zooglooa masses in their early stages are colourless, but a large proportion of them are, as I maintain, ultimately destined to give rise to brown Fungus-germs. The assumption of the brown colour may, however, be taken on by the segments of the Zoogloea while they are still only aggregates of bacteria, as may be seen by fig. 2, A, showing nearly spherical segments of a large Zoogloe mass which were in different shades of brown, and in some of which the constituent bacteria (now themselves coloured) are plainly to be seen. The same thing occurs not unfrequently in Koogloca masses which have as yet undergone no segmentation, as in fig. 2, D. In B a small Zoogloea aggregate is seen becoming brown, the process being rather more advanced below
than above, while in C a similar mass is to be seen which has ahmost completely segmented into Fungu-germs. In E we have two other much smaller masses of Zoogloe which have become brown, and which plainly show their constituent bacteria ; while in F we have the same process taking place in very minute units of Zoogloa, such as give rise to discrete Fungus-germs-though in other cases very similar minute units of $Z$ oogloea, to which I shall presently refer, are transformed either into Monads or into Amœbre.

These facts concerning the changes taking place in large or small masses of Zoogloa, even leaving aside the question of their subsequent transformations, are surely facts of considerable importance well worthy of a little attention on the part of bacteriologists.

Although my more complete recent observations as the assumption of a brown colour by the Zoogloa masses and their segments serve to make the relationshipbetween them and the brown Fungus-germs more obvious than it was previously, yet the actual proof of the development of the one from the other can now be given in a more complete way-also as a result of recent observations.
(2) The Transformation of Zoogloa Musses into Fungusgerms or Monads.-The very distinct specimens to which I shall first refer were taken from the scum on a hay-infusion that had been exposed in a small closed pot to a temperature of $70^{\circ} \mathrm{F} .\left(21^{\circ} \mathrm{C}.\right)$ for seven days. Many of the Zoogloa masses had by that time become wholly transformed into brown Fungus-germs, though other masses in all intermediate stages were to be seen. Some were still in an early colourless state, as in fig. 1, A, the mass there represented having been taken from this infusion. A later stage in which the whole mass is being converted into embryo Fungusgerms is shown in fig. 3, A; and a still later stage, in which the nucleated embryo germs are far more distinct, is shown in B. In C the germs may be seen to be larger and becoming brown, while in D (shown under a lower magnification) the entire mass of the Zoogloa has been transformed into aggregates of brown Fungus-germs.

In the pot from which these specimens were taken at the end of the seventh day not a single hypha was to be found, nor were there any of the thick-walled brown cells to which Mr. Massee refers *. All such bodies were similarly absent for many days after, during which from time to time I

$$
\text { *'Nature,' Nec. } 2.2,1004, \text { p. 17\%. }
$$

examined the contents of the pot. It was perfectly plain, indeed, that in the thousands of small Zoogloca masses undergoing this change, one had to do with no process of infection. It was clear that the Zooglœa masses were becoming organized simultancously throughout their substance, and that all the stages of the development of the Fungus-germs into which they were being transformed could be more or less plainly traced, the changes in this case taking place without any antecedent minute segmentation of the masses. I invited Mr. Massee to come and examine these specimens for himself, but he did not do so, and nevertheless subsequently thought proper to write the letter already referred to, which appeared in 'Nature,' and was answered in a subsequent issue (January 19, 1905, p. 272).

A similar transformation of the Zoogloea masses without antecedent segmentation has been seen in other cases, though in none of them have I been able to make out the actual stages of the transformation anything like so plainly as in the specimens represented in fig. 3. In one of the cases recently seen, in which the specimens were also taken from a closed lot, the Zoogloea masses as a whole had previously assumed a pale brown tint, and rather large Fungus-germs were formed from their substance, such as are shown in fig. 4, A $(\times 700)$. But, again, no hypha of any kind was ever seen among the contents taken from this pot.

Where a certain amount of segmentation has occurred in the Zoogloa mass before the brown colour is assumed (as in fig. 2, A, in which the constituent bacteria are still distinct), these brown segments subsequently become resolved into Fungus-germs, as may be seen in fig. 4, B. Such brown Fungus-germs soon assume more definite contours as in A, and they may occasionally, but very rarely, be seen to give rise to hyphr.

As intimated in my previous communication to 'Nature,' there are various modes in which Fungus-germs originate from the Zuogloea masses. Still these different modes are only comparatively unimportant variations, dependent upon the different states of the Zoogloea masses at the time when the actual transformations take place. The principal variations seem to be these:-
(a) Zooglœa entire and uncoloured ; organization throughout, and Fungus-germs when forming becoming brown, as in fig. 3.
(b) Zoogloa entire, but assuming a brown colour before the transformation into Fungus-germs occurs, as in fig. 2, D, and fig. 4, A.

Ann. © Mag. N. Hist. Ser. 7. Vol. xv.
(c) Zoogloa uncoloured, undergoing partial segmentation, and then the origination therefrom of Fungus-germs gradually becoming brown, as in figs. 8 and 9 in 'Nature' for Nov. 24 th, 1904.
(d) Zoogloea uncoloured and undergoing partial segmentation; these segments then becoming brown, and subsequently being transformed into groups of brown Fungus-germs, as in figs. 2, A, and 4, B.
(e) A mixture of the last two processes, as shown to some extent in the lower part of fig. 9 ('Nature,' Nov. 24th).
( $f$ ) Zoogloca uncoloured and undergoing complete segmentation into colourless units, which gradually assume a brown or brownish-black tint, as in fig. 12 ('Nature,' Nov. 24th).

As I previously said, the conversion of the Zoogloea masses into aggregates of Monads takes place much less frequently than their transformation into Fungus-germs. Still the two processes may often be seen going on side by side in the pellicle. I am, indeed, disposed to think from what I have seen that some of the same kind of Zooglœa masses which in the early days become converted into Monads may, if they chance to remain untransformed for seven or eight days, be then converted into Fungus-germs rather than into Monads. It is difficult to be certain of this, but I am strongly disposed to believe that it is so. It is quite certain, however, that conversion into Monads, when it occurs, takes place almost always somewhere between the third and the fifth days, while after the latter date up to the tenth or twelfth day one finds Zoogloea masses either all brown or producing brown segments which are being converted into Fungus-germs. The Zoogloca masses and all the segments into which they divide invariably remain colourless where Monads or Amœbæ are to be the products.

Since my former communication to 'Nature' I have seen enormous numbers of the Zoogloca masses yielding Monads in the pellicle on an infusion of hay, which was exposed to light in a small beaker. The Monads were met with on the fourth and fifth days, the temperature to which the infusion had been exposed having varied from about $54^{\circ}-59^{\circ} \mathrm{F}$. $\left(12^{\circ}-15^{\circ}\right.$ (.). The Zoogloca masses were in many cases very large and presented some peculiar characters. In their early stages they always appeared as pellucid, somewhat ramified, discontinuous areas, as shown in fig. 5, A (Pl. XV.). Later, portions of the mass begin to segment as in B ; later still, actual Monads may be seen beginning to form, as in fig. $6, \mathrm{~A}$; while, finally, there is a more complete conversion into an aggregate of
motionless spherical or ovoidal units, as shown in fig. 6, B, which after a time become active flagellate Monads.

As I have indicated in my 'Studies in Heterogenesis,' pp. 69-73, Monads are much more commonly proluced from the pellicle in another way-namely, as pale, discrete, motionless corpuscles more or less thickly distributed through its under layers. These are to be seen often in the course of the third or fourth day, when not a single active Monad has hitherto been found. While if the same pellicle be examined twelve or twenty-four hours later, the fluid may be discovered to be swarming with active Monads, all of about the same size, and this size agreeing with that of the previously motionless corpuscles. At other times swarms of minute Amoebr rather than of Monads suddenly make their appearance where only motionless corpuscles were previously present.

As the corpuscles sometimes develop into Monads and sometimes into Amœbæ, I have been accustomed to speak of them as "indifferent corpuscles." Not unfrequently, however, after their formation they may remain for a much longer time quiescent and without developing in either direction. This was the case in a hay pellicle that I have recently examined, in which such corpuscles were found in enormous numbers and rather larger than usual. They were first seen when a small pot containing same hay-infusion was opened after four days, during which it had been exposed to a temperature of $70^{\circ} \mathrm{F} \cdot\left(21^{\circ} \mathrm{C}.\right)$. The edge of a portion of this pellicle is represented in fig. 7, A, while in B some of the separate corpuscles are shown more highly magnificd, so as to reveal the nature of their contents. Nothing like a nucleus is to be seen, nor can one be detected by the use of any of the ordinary stains even when the corpuscles have been allowed to soak in them for many hours. Logwood, carbo-fuchsine, gentian violet, and mastzellen stain have all yielded negative results. Not a trace of a nucleus is to be found, and the corpuscles seem to be mere individualized portions of Zoogloa intermediate in size between the brown units on the way to the production of Fungus-germs, which are shown in fig. 2, E and F , and, like them, containing only a few bacteria in their interior. I have examined such corpuscles over and over again, and always with similar results. If they do not speedily develop, a limiting membrane is produced which enables their contents to resist staining, and causes the corpuscles themselves to shrivel if they are mounted in glycerine and water. When these corpuscles develop quickly, which is the rule, they give rise, as I have said, more or less suddenly to swarms either of Monads or of minute

Amobre, and then, when thus developed, a delicate nucleus can generally be recognized even without the aid of stains.

Of course all this is very contrary to generally accepted beliefs; but if others would only investigate this subject with care, as I have done, I have little doult but that my results would speedily be confirmed. The study of what goes on in the scum on a hay-infusion might, indeed, be strongly recommended to some who are occupied with researches on the origin of species, and the phenomena of variation in vegetal and animal organisms, as likely to yield more fundamental and more striking results than certain statistical and other methods of enquiry which at present find favour.

In conclusion, I would ask, Why do the bacteriologists not tell us what they know about Zoogloa-whether they are or are not aware of its developmental tendencies, and why it should undergo processes of minute segmentation, unless such processes are a result of an organizing tendency destined to have some definite outcome? Why, again, should it or its segments so often tend to assume a brown colour, while it is still nothing but Zoogloea, either segmented or unsegmented? Again, why, if the brown Zoogloea does not yield the brown Fungus-germs, should there be this constant association of myriads of brown Fungus-germs (in the absence of hyphæ) in association with brown masses of Zoonloea? How can they explain, other than I have done, the actual organization of a Zoogloea mass and the stages by which the brown Fungus-germs seem to be formed therein, such as are shown in fig. 3? What process of "infection" in a filtered hayinfusion contained in a closed pot could cause thousands of small Zoogloea masses to go simultaneously through similar processes of this kind-producing myriads of brown Fungus-germs-when not a single hypha is anywhere to be found, and where at first no Fungus-germs are to be met with outside the Zooglœa masses themselves? I trust the bacteriologists will vouchafe to give us some information on these points, or, if they cannot reasonably explain them, that they may be induced to work at the subject, and satisfy themselves that something important can be learned concerning bacteria, even though it be outside their laboratories and by methods other than their own.

## EXPLANATION OF THE PLATES. <br> Plate XIV.

Fig. 1. A. An ordinary mass of Zoogloa in an early stage.
B. A more pellucid mass in which the glowal material is unusually abundant.

Fig. 1. C. Portions of a large Zooglœa mass at a later stage in which the contained bacteria are still distinct, though altered, within the segments.
D. Glistening serments of a Zoogloa mass in which the bacteria are completely obscured, while by their side are other segments which have become resolved into brown Fungusgerms.

$$

XXVI.-Descriptions of new Species of Sphegidx and Ceropalidæ from the Khasia Hills, Assam. By P. Caneron.

## Sphegidæ.

Crabro himalayensis, sp. n.
Length 10 mm . $\quad$.
Belongs to Bingham's (Fauna of Brit. India, Hymen. i. p. 322) division "B. Abdomen non-petiolate" and to a new section "Enclosed space at base of median segment punctured."

Black; the antenual scape beneath, two broad lines on the top of the pronotum, and marks on the sides of the abdominal segments, yellow; wings almost hyaline, the stigma fuscous, the nervures darker in colour. Vertex sparsely, the front more strongly and closely punctured and thickly covered with longish black hair; the lower part of the front, face, and clypeus covered with silvery pile. Mesonotum closely, the scutellum more sparsely punctured, its base in the centre smooth. Metanotal area distinctly punctured, the sides with a fer indistinct strie, the middle with a broad and deep longitudinal furrow, which has a few transverse striæ; the apical slope has, on the top, some minute scattered punctures, its apex and sides finely and closely transversely striated; the middle furrow is deep; the furrow bounding the enclosed space striated. Upper part of propleure indistinctly striated, the lower with two distinct divisions of curved strice. Mesopleural furrow decp, crenulated, the part at its base striated. Basal half of metapleure closely, minutely, obliquely striated. Mesosternum covered with longish, soft, white hair.

## Crabro monozonus, sp. n.

Black; a broad yellow line on the pronotum, one on the apex of the sccond abdominal segment, the apex of the anterior femora broadly, the fore tarsi and the anterior tibire in front, yellow. Wings smoky fuscous, the nervures and stigma black. 우.

Length 9 mm .
Metanotal area ohliquely striated, but not strongly, and with a narrow furrow down the centre. Front and vertex opaque, closely and distinctly punctured and corered with long blackish hair; there is no furrow below the ocelli. Face and elypeus thickly covered with silvery pubescence;
the latter not keeled in the middle, its apex broadly rounded. Mesonotum and scutellum closely punctured, the former with a narrow keel down the middle. Pleuræ smooth, thickly covered with short white hair; the furrows crenulated. Fore tarsi covered with broad leaf-like spines. Pygidium not depressed, keeled, or punctured. Abdomen sessile.

## Cerceris.

## a. Metanotal area punctured.

## Cerceris bimaculata, sp.n.

Black; a large semicircular mark on the cheeks touching the eyes, a triangular mark below the antennal kecl, the clypeus (except for a broad black line on the apex), a broad band on the pronotum, the sides of the scutellum broadly, the base of the second abdominal segment, almost the apical half of the third, and a narrow interrupted line on the fourth and fifth segments, rufous. Wings smoky fuscous, lighter behind, the stigma fulvous. $q$.

## Length 10 mm .

Front and vertex closely and strongly, the cheeks closely and less strongly, and clypeus more sparsely punctured. Apex of clypeus slightly waved, the outer of the three projections the larger. Antennal keel stout, black. Mesonotum closely, rugosely punctured. Metanotum with area closely punctured, the apex with two shining forer. Mesopleurie reticulated, the pro- and metapleuræ aciculated. Pygidium irregularly rugosely punctured; the sixth ventral segment has on the sides, at the apex, a patch of fulvous pubescence; the hypopygium entire.

May be known from C. Timalayensis and canaliculata by the scutellum being broadly rufous at the sides. The four anterior tibire and the anterior tarsi in front are testaccous.

## Cerceris canaliculata, sp. n.

Black; the face, lower inner orbits widely, clypeus (except at the apex), a band on the pronotum, the base of the second abdominal segment, the apical half of the third, and a narrow line on the sides of the fourth segment, rufous. Wings fuscous, if anything darker in front, and with a slight violaceous tint. Leys black, the four anterior tibie testacesus in front. $\delta$.

Length 10 mm .

Metanotal area closely and distinctly punctured ; the sides obliquely striated; on the apex of the segment are three furrows, the central being the larger ; the hair on it is long and fuscous. Lower orbits and sides of elypeus covered with pale golden pubescence. Front and vertex elosely and somewhat strongly punctured and covered with long fuscous hair; the face and clypeus less strongly punctured. Mesonotum and scutcllums closely and strongly punctured. Propleure aciculated, the middle of the mesopleure reticulated, the perpendicular strie more distinct than the longitudinal; the metapleure aciculated. Pygidium only slightly narrowed at the extreme apex, being of almost equal width throughout; it is irregularly rugosely punctured, except at the apex.

Belongs to Bingham's section B: C. himalayensis differs from it in the apex of the clypeus broadly projecting and transverse, whereas in the present species it is broadly rounded; this species wants the yellow marks behind the cyes and the central furrow on the apex of the median segment is clearly defined.

## Cerceris himalayensis, sp. n.

Black; the face, inner orbits widely, the antennal keel, clypens (except at the apex), and a small spot behind the eyes near the top, rufous; a broad line on the pronotum, scutellums, a broad band on the hase of the second abdominal segment, a narrower one on the apex of the third, a narrow one on the apex of the fourth, and a narrow interrupted line on the apex of the fifth, yellow. The four anterior tibire yellowish in front. Wings hyaline, the basal half of the anterior and the radial and cubital cellules smoky ; stigma fulvous, nervures black. if.

Length 10 mm .
Front and vertex strongly and closely punctured, the front more coarsely than the vertex; the clypeus sparscly, the cheeks closely and coarsely punctured. Apex of clypeus with a slight broad incision. Mesonotum closely, the seutellum, if anything, more strongly punctured ; the metanotal area closely rugosely punctured. Pro- and metaplcure coarsely aciculated ; the mesopleure coarsely punctured, above the middle, on the basal half, is a wide longitudinal furrow. Median segment above thickly covered with long fuscous hair. Pygidium closely rugosely punctured ; the apex of the hypopyginm almost transierse.

## Cerceris intimella, sp. n.

Black; the clypeus (except at the apex), the inner orbits broadly to the top of the antennal keel, the keel, a spot behind the top of the eyes, a line on the pronotum, the scutellums, the apex of the first abdominal segment, the base of the second more broadly, the apex of the third, and a narrow more or less interrupted line on the fourth and fifth, yellow. Wings lyaline, broadly fulvous smoky in front, the costa and stigma fulvous, the nervures fuscous. Four anterior tibie testaceous in front. $q$.

Length almost 15 mm .
Front and rertex closely distinctly punctured, more closely and finely behind the ocelli ; clypeus sparsely punctured, the apical incision large, semicircular; the pubescence on the lower part of the iuner orbits dense and silvery, on the rest long, fuscous. Pronotum closely and minutely, the mesonotum and scutellum closely distinctly, the postscutellum closely minutely, punctured; the scutellum with a slight depression in the middle. Metanotal area closely strongly punctured like the rest of the segment; the pubescence on it is black. Pro- and metapleure alutaceous, the former with a few obscure striæ, the latter irregularly striated at the base; the mesopleure strongly punctured. Pygidium closely irregularly reticulated, becoming slightly narrowed from the middle to the aper.

Comes into Bingham's section B. $b$.

## b. Metanotal area striated.

## Cerceris rufoplagiata, sp. n.

Black; the scape and pedicle of the antenne, the inner eye-orbits from opposite the base of the antennæ, the antennal keel, a mark on the top of the clypeus, and its outer edge below, yellow ; the upper part of the prothorax, the apex of the mesonotum in the middle and at the sides, the scutellums, a mark on the propleuræ, one behind the tubereles, the tubercles, the first abdominal segment above, with a black mark in the middle behind, the base of the second broadly, its apex narrowly, the apical two thirds of the third, and the apices of the following three segments narrowly, rufous. Wings smoky hyaline, darker in front, the stigma fulvous. Legs black, the anterior femora and tibie red. $i+$

Length 7 mm .
Front and vertex strongly, closely, and uniformly, the face less closely punctured, almost smooth in the middle.

Clypeus broadly rounded in the middle at the apex and densely covered with silvery pubescence. Mesonotum and scutellum rather strongly punctured. Metanotal area obliquely striated, the rest strongly and rather irregularly punctured. Propleure strongly obliquely striated; the mesopleuræ (except at the base) strongly and uniformly punctured. The base of the metapleure smooth, irregularly and finely striated above and below, the apex rugose. Pygidium rather strongly, but not very closely punctured.

The obliquely striated metanotal area brings this species into Bingham's section C. $b$ near to C. Elizabethe.

## Cerceris aureobarba, sp. n.

Black; the clypeus (except at the apex), a mark above it, produced on the top into a narrow point, a large semicircular mark on the face touching the eyes, the third abdominal segment (except at the base), and the apices of the fourth, fifth, and sixth narrowly, yellow. Legs black, the four anterior tibir (except for a black line behind) and the basal joint of the tarsi yellow. Wings hyaline, smoky in front. $\delta$.

Length 9 mm .
Belongs to Bingham's section C. $b$.
Front and vertex strongly and deeply punctured, the punctures rumning into reticulations and on the front into strie ; the clreeks and clypeus covered with silky pubescence, the sides of the clypeus fringed with long golden hair. The sides of the pronotum, tegulæ, and postscutellum rufous. Pro- and mesonotum rugosely punctured, the centre of the former irregularly striated behind. Metanotum stoutly obliquely striated; the rest of it is more strongly punctured than the mesonotum. Top of propleure smooth, with three fover, the middle has three stout curved strix, the lower part irregularly rugose. Mesopleure rugosely punctured (except behind, where it is finely striated above, aciculated below). Netapleure rugosely punctured, the base stoutly obliquely striated. Base of pygidium stoutly punctured, minutely punctured between ; the hypopygimm is roundly, but not decply, incised at the apex.

> c. Metanotal area smooth.

Cerceris lepcha, sp. n.
Black; the antennal scape below, a large mark on the face, triangular above, the inner orbits, the clypeus (the
yellow reaching to the cyes), the greater part of the antemal keel, the base of the mandibles, a line on the pronotum, the greater part of the scutellum, postscutellum, a line on the sides of the apex of metanotum (rounded above, transverse below), yellow. The base of the second abdominal segment all round pallid yellow, the apical two thirds of the second, the apex of the fifth, and the apical segments entively, rufous yellow. Legs black, the anterior tibire testaccons; all the knees, trochanters, and the extreme base of the tibire yellow. Wings hyaline, the radial and the apical cubital cellules smoky, the stigma and nervures black. $\delta^{\pi}$.

Length 8 mm .
Basal joints of antennal flagellum brownish beneath, as are also the apical more obscurely. Front and vertex strongly but not very closely punctured; thickly covered with white hair, as are also the face and clypeus. Mesonotum shining, sparsely punctured, thickly covered with short white hair. Scutellum furrowed down the centre. Median segment sparsely punctured; the central furrow shallow and ending at the apex in two distinct forere; the basal area smooth and shining. Lower side of propleure with some curved stria; ; the mesopleura strongly punctured; the apex of the metapleure sparsely punctured and thickly covered with white hair. Pygidium strongly, but not closely, punctured.

Tachysphex bituberculata, sp. n.
Length 11 mm . $\quad$.
Black; the head and thoras densely punctured, the upper part of the front covered with a short pile, the lower, laterally, thickly with silvery pubescence, the middle furrowed ; above the antenne are two shining, smooth, oblique tubercles. Face and clypeus closely punctured, thickly covered with silsery pubescence; the apex of clypeus obliquely depressed, smooth and shining before the middle; the apex projects broadly in the middle. Base of mandibles thickly covered with silvery pubescence. Mesonotum thickly covered with short white pubescence. Scutellum more shining, and, if anything, more widely punctured than the mesonotum. Base of metanotum closely reticulated all over; the oblique apex rugose and furrowed narrowly in the middle. Propleure above closely rugosely punctured, below shining, aciculated, and sparsely punctured. Mesopleure elosely distinetly punctured ; behind the base is a wide, not very decp furrow obscurely striated; immediately below the
tegula is a deep depression, with an oblique slope at the base. The upper part of metapleure with some sharp, irregular, distinct, clearly separated keels; the rest closely covered with strie, which become stronger towards the apex. Legs pruinose, the anterior calcaria and spines pale. Wings hyaline, the apex with a narrow fuscous band; the nervures behind the stigma pale yellow; the first recurrent nervure is received shortly behind, the second in the middle of the cellule. Abdomen with brown pruinose bands; pygidium bare, aciculated, its apex more shining and distiuctly punctured laterally; the sides sharply keeled; base of hypopygium smooth, the rest punctured.

## Notogonia fuscinerva, sp. n.

Length 13 mm . $q$.
Agrecs in coloration with N. subtessellata; may be known from it by the first transverse cubital nervure not having a gradual curve from the top to the bottom, but is distinctly elbowed; the second recurrent nervure is not so oblique, its bottom being opposite to its top, this being not the case with $N$. subtessellata, and the apices of the metasternal lobe are broader and more rounded.

Black; densely covered with a silvery pile, the pile on the mesonotum darker, more golden in tint. Wings hyaline, iridescent, the aper steel-blue, the nervures fuscous; the first transverse cubital nervure is distinctly elbowed in the middle, the two parts having an oblique straight slope; the second cubital cellule has the length of the third; the two recurrent nervures are received before the middle; the apex of the radius has an oblique slope. Legs thickly pruinose; the hind femora red, except at the extreme apex; tarsal spines rufous.

Head aciculated, the three depressions on the front deep; the central furrowed down the middle. Apex of clypeus smooth, glabrous, and with a small incision in the middle. Base of mandibles covered with depressed silvery pubescence, the middle rufous; palpi black, thickly covered with white hair. Median scgment closely transversely striated; the furrow on apex deep and with oblique sides. Metasternal process broad, its sides raised, the apex incised, the lateral lobes broadly rounded. Abdominal segments broadly banded with silvery pile ; the pygidium thickly covered with silvery, inclining to golden, pubescence ; the hypopygim punctured, strongly at the apex.

## Notogonia aciculata, sp. n.

Black; covered with a silvery pile; mandibles dark piccous towards the apex ; palpi dark testaccous and thickly covered with white pubescence. The wings from the transverse basal nervure distinctly fuscous-violaceous, behind it hyaline. Abdominal segments banded with silvery pubescence; the pygidium closely punctured and thickly covered with pale pubescence; the basal ventral scgment strongly obliquely striated. $\quad$ ㅇ.

Length 9 mm .
Front and vertex alutaccous; ocellus longer than broad, rounded, and having a longish narrow pedicle in front; frontal furrow deep and obliquely widened above ; the depression on vertex shallow, indistinct. Pro- and mesonotum coarsely aciculated, the base of metanotum closely transversely striated ; a narrow keel down the middle; on the sides of the apical slope are oblique, clearly separated strice; in the centre of the apex is a $\cap$-shaped area indistinctly keeled in the middle. Propleuræ aciculated. Mesopleuræ distinctly and closely punctured ; the metapleure strongly obliquely striated on the basal half, the apical aciculated strongly and obscurely striated. Apical lobes of sternal process rounded; the middle furrow is narrow. Second cubital cellule not much more than half the length of the third; the first transverse cubital nervure curved, the second recurrent is received distinctly behind the middle of the cellule, the two are separated by about the length of the front of second cubital cellule.

## Notogonia khasiana, sp. n.

Length 10 mm . $\quad$.
Agrees with N. aciculata, but is stouter, the wings not so distinctly hyaline at the base, the second cubital cellule longer compared with the third, the apical slope of the median segment is not so distiuctly striated, the metapleure are only indistinctly striated at the base and apex, and the upper half of the first transverse cubital nervure has a straighter more oblique slope.

Ocellus longer than broad, triangularly produced in frout; the lower part of the front, face, and clypeus thickly covered with silvery pubescence. Mandibles obscure brownish in the middle. Palpi black, thickly covered with white pubescence. Mesonotum closely minutely punctured. Median segment with the basal two thirds finely transwersely striated and furrowed down the centre ; the sides of apex obseurely
irregularly striated; on the sides of apex are four oblique keels. Pijcure aciculated ; the base and apex of the metapleure with a few oblique keels. Sternum thickly covered with silvery pubescence; the process bluntly triangular on the sides at the apex; the central part has the basal half distinctly dilated. Wings fuscous-violaceous; the sceond cubital cellule is, if anything, shorter than the first; the first transerse cubital nervure is obliquely bent from shortly below the middle; the second recurrent nervure received shortly beyond the middle of the cellule; the two nervures are separated by the length of the top of the sceond cubital cellule. Legs and abdomen pruinose; the pubescence on the pygidium bright fulvous; the leg-spines blackish.

## Notogonia vivax, sp. n.

Black; the body and legs covered with silvery pubescence, the leg-spines black; wings hyaline, with a slight but distinct yellowish tint, the apex smoky; the costa, stigma, and nervures testaceous, the apical nervures darker ; the second cubital cellule in front half the length of the third; the recurrent nervures received behind the middle and separated by slightly less than the length of the second cubital cellule in frout. Pile on pygidium silvery, with a slight golden tint ; the hypopygium closely and distinctly punctured. $q$.

Length 12 mm .
Front and vertex alutaceous; the ocellus rounded behind, in front produced into a process as long as itself, the furrow below it dcep. Mesonotum alutaceous, the pile with a yellowish tint ; proplcurse stoutly irregularly striated in the middle. Median segment alutaceous, the apical slope transversely striated, the strize on the lower part finer than on the upper. Metapleure finely and closely obliquely striated.

This species has the yellowish-hyaline tinted wings of N. tristis and N. jaculatrix: the former may radily be known by the reticulated median segment; the latter is a larger and stouter insect, has the second cubital cellule on the top longer compared with the third, the tibial spines are shorter and rufous, not black, the pubescence on the front longer and denser, and the ocellus has ouly a short projection in front.

Notogonia tegularis, sp. 1.
Black; the checks, face, and clypeus thickly covered with silvery pile; the front and vertex with fuscous hair; thorax
thickly covered with whitish pubescence, the pleure with a silvery pile. Legs densely covered with silvery pile; the tibial and tarsal spines, claws, and base of spurs rufous. Wings fuscous-violaceous, the nervures fuscous; the second and third cubital cellules equal in length in front; the second recurrent nervure received in the middle. Abdomen closely punctured and covered with pale pubescence; the apices of the second and third segments smooth, depressed; the penultimate segment and the pygidium thickly covered with fuscous pubescence, as is also the ventral surface. Tegulæ pale testaceous. $i$

Length 13 mm .
Front strongly punctured above, distinctly furrowed down the middle, the lower part smooth and shining, widely furrowed, the furrow divided in two ly a raised point; the lower part of vertex sparsely punctured, the upper smooth; the lateral depressions on front wide, the upper transverse one the decpest. Clypeus closely punctured (except at apex), its base thickly covered with fuscons pubescence. Mesonotum and scutellum closely punctured. Metanotum closely transversely striated, the strix more widely separated at the base, where there is a small somewhat triangular keel. Metasternal process closely punctured, its base depressed; the two apical lobes rounded.

## Notogonia testaceicornis, sp. n.

Black; the antennal scape rufous below, the flagellum rufo-testaceous, darker at the base; wings fusco hyaline, the nervures testaceous, the second cubital cellule in front half the length of the third. Legs thickly covered with white pubescence; the tarsal spines and claws rufous. $\delta^{\top}$.

Length 14 mm .
Comes near to $N$. tegularis; may be known from it by the second cubital cellule not being as long as the third.

Face, cheeks, and clypeus thickly covered with silvery, the vertex with fuscous, pubescence. Vertex almost impunctate; the ocellar region faintly behind, strongly and closely in front, punctured, broadly depressed, furrowed before the ocelli. Front smooth and shining above, the furrow smooth and shining, the upper part the larger. Clypeus (except at apex) closely punctured, the apex rounded. Mandibles rufous before the middle, the base punctured, thickly covered with white hair. Palpi dark testaceous. Mesonotum closely punctured, thickly covered with fuscous pubescence; the scutellum more shining, less closely punc-
tured; postscutcllum much more fincly and closely punctured. Median segment closely and finely transversely striated and thickly covered with white pubescence. Metapleure (except at the base) finely punctured. Metasternal process raised in the middle behind and keeled in the centre of the raised part; the apical lobes rounded. Abdomen fincly punctured, the apices of the basal four segments depressed; the middle and apical segments thickly covered with silvery pubescence; pygidium thickly covered with silvery pile; the penultimate segment bears long fulvous hair. Ventral surface thickly covered with silvery pubescence; the apical also with fuscous hair.

## Noloyonia strenua, sp. n.

Black, covered with silvery pubescence; pro- and mesothorax closely and distinctly aciculated, the clypeus smooth; front and vertex alutaceous, almost punctured; the lower furrow wide and deep. Basal part of median segment closely, distinctly, transversely striated, almost reticulated; the apex finely, but not very closely, transversely striated; the furrow deep, narrowed in the middle. Netapleure finely, uniformly, and closely obliquely striated. Sternal process depressed in the middle at the base, the apical incision long, not quite reaching backwards to the middle, the apical lobes romided. Aldominal segments banded with silvery pubescence; the pubescence on prgidium white. Legs densely pruinose; the spines black. Wings fuscousriolaccons, the stigma and nervures black; the second cubital cellule in front about tro thirds of the length of the third; the first transverse cubital nervure roundly curved and clearly bullated below the middle; the recurrent nerrures are received shortly behind the middle and separated by about half the length of the second cubital cellule; the apical abscissa of radius is long, straight, and oblique. $q$.

Length 12 mm .
Ocellus longer than broad, its apex sharply pointed. Clypeus smooth and shining. Mandibles piccous before the apex.

## Notoyonia sulcifions, sp. n.

Black, densely covered with silvery pubescence. Mandibles ferruginous, the base black, covered with white hair ; palpi fuscous black, covered with white pubescence. Legs thickly covered with silvery pubescence, that on the femora
long; the tarsal spiwes and calcaria rufous. Wings uniformly fuscous-violaceous, the nervures black. Abdomen thickly pruinose; the basal three segments broadly depressed at the apex, the apical two thickly covered with fulvous pubescence, the ventral surface thickly with pubescence, which is pale on the basal, darker on the apical, segments. if.

Length 13 mm .
Front and ocellar region distinctly punctured; there is a broad deep furrow below the ocellus. Face and clypeus thickly covered with silvery pubescence ; the apex of clypeus rounded, smooth, bare, and shining. The white hair on the thorax is thicker and longer on the pleuræ, and, to a less extent, on the apex of metanotum. Mesonotum and scutellum punctured all over, but not closely or strongly; the postscutellum is more weakly punctured. Metanotum finely, closely, transversely striated. The lower part of the pro- and mesopleure striated at the apex. Sternal process has a broad keel down the middle, the apical lobes rounded. Second cubital cellule in front one third of the length of the third; the first recurrent nervure is received the length of the top of the second cubital cellule from the base, the second shortly behind the middle of the cellule.
[To be continued.]

## BIBLIOGRAPHICAL NOTICES.

## Trouessart's ' Catalogue of Mammals.'

Catalogus Mammalium, tam Viventium quam Fossilium. By E. L. Irouessart. Quinquennale Supplementum: Pt. 2. Rodentic. Berlin, 1904. Pp. 289-546. Price 12s.
Since the general remarks which appeared in our notice of the first part of the reissue of this raluable Catalogue apply also to the one before us, our comments on the latter may be relatively brief. It is highly satisfactory to find that Dr. Trouessart is making such good progress with his arduous task, this fasciculus bringing the work down to the end of the Rodents. Of course there are faults in this part, as in its predecessor, for no human being could possibly carry out such a piece of work without making some errors; but such mistakes as hare come under our notice are trivial, and in no wise detract from the value of the Catalogue or from the credit due to the indefatigable anthor for carrying out his task so thoroughly. 'The value of this Catalogue to practical workers is simply inexpressible.

Comparing the present classification of the Rodentia with that adopted a dozen years ago, the most notable changes (apart from those in the nomenclature and the number of generic and subgeneric
divisions of some of the existing groups) are to be found among the extinct forms. We notice, for example, the inclusion in the order of a number of Eoceno genera, such as Plesiadapis, Indrodon, and Microsyops, which were originally regarded as lemuroids or insectivores, but are now considered by American palieontologists to represent a primitive group of rodents-the Protoglires. Whether this identification is well founded remains to be scen. Another important and apparently well-justified change is the transference of the Oligocene and Miocene Trechomys, Theridomys, and their allies from the neighbourhood of the Octodontide to a position in the Siciuromorpha between the Anomaluride and the Sciuride. The extinct Maltese Leithia, together with I'seulosciurus and Sciuroides, is now definitely placed in the Anomaluride, although the right of the latter to retain its position in the Sciuromorpha is only provisionally admitted.

In accordance with adranced modern vierss, we find the old genus Sciurus split up into a number of separate generic groups; and we note many other changes in nomenclature, such as the substitution of Jacnlide for Dipodidæ, thus showing that the author is keeping his work well abreast of the latest imovations. Why, however, Myoxidæ is retained in place of Gliridæ is not easy to understand; and the substitution of the name Agoutide for Dasyproctidæ, on account of the replacement of the generic term Ceeloyemys by Agouti, seems altogether uncalled for, seeing that Dasyprocta still remains as the generic title for the agutis. The number of new specific names proposed in this fasciculus appears to be very small.
R. I.

## Muserm Ifandbooks. <br> The Manchester Museum, Owens College. 1904.

Under the direction of Dr. W. E. Horle, the Director, papers relating to the Manchester Museum and its contents are from time to time issued to the public. For the most part these are gathered from various serial journals, consequently their re-issue in the present form will be welcomed.

Three of these are now before us, of which two deal with matters palæontological and one with recent Cephalopods.

Mr. II. Bolton's 'Palæontology of the Lancashire Coal-Measures' prorides a useful summary of this subject, especially helpful to those working in the museum, where the specimens described are deposited.

Prof. W. Boyd Dawkins has prepared the second of these paleontological pamphlets, 'On the Discovery of Elephes antiquus at Blackpool.' He takes for his text the finding of a tooth of this species, which he, with the aid of his wife and son, dug up by the aid of umbrellas! llaving described the tooth he passes on to discuss the question, "How did the tooth . . . . come to be embedded in the Lower Boulder-Clay?" In answering this question the author gives some interesting aud valuable information on the deposition of the boulder-clay and of other fossil Mammalia found in association with this Elephant.

Dr. Hoyle's ' Diagnostic Key to the Genera of Recent Dibranchiate Cephalopoda' is necessarily extremely technical, but it will, without question, prove invaluable to those desiring to identify adults of this group.

We venture to think the prices charged for the papers by Dr. Hoyle (one shilling and sixpence) and Mr. Bolton (one shilling) a little high, at least when compared with the wonderful shillingsworth provided by the authorities of the Natural History Museune at s. Kensington. But probably the authorities of the Manchester Muscum cannot afford to publish these handbooks at a loss, or at least with but an infinitesimal profit!

## MISCELLANEOUS.

On a Marine Pseudoscorpion from the Isle of Man. By A. D. Isms, B.Sc. (Lond.), Zoological Laboratory, University of Birmingham.

About the shores of Port Erin Bay, during August 1904*, I came across a species of psendoscorpion which frequented the rocks about halfway between the limits of high and low tides. The fact of this being so unusual a habitat for an animal belonging to this order led me to make a careful search for it, but it resulted, however, in my obtaining only five individuals. They were found to agree in all respects with Obisium maritimum, Leach, and I am indebted to the Rev. O. Pickard-Cambridge, F.R.S., for contirming my identification of that species.

Four of the specimens were found deep in the crannies and fissures with which the slaty rocks of the locality abound, while the fifth example was met with in the act of crawling over the rocks and weed. The first specimen was obtained while searching for the eggs of the marine Collembolan Anurida maritima. To discover the latter it is necessary to be provided with a stout hammer and chisel in order to split open the fissures in the depths of which they are deposited. In the recesses of these fissures there are to be found, in addition to the pseudoscorpion, adults of Amarida maritima, larvx, pupx, and imagines of the Coleopteron Nicralymme brevipenne, and numerous individuals belonging to a species of an Acarus, which I have not yet been able to determine. It is probable that the Obisium preys upon the Collembola and most likely upon the Acari also. When alarmed or irritated, it was observed to run about actively in both a forward and backward direction with outstretched pedipalps, but it was not seen to run sideways, as is known to be the case with some pseudoscorpions.

The nature of the habitat of Obisitm and of the other Arthropods associated with it is such that they have to endure submersion twice every twenty-four hours. Unlike Anurida (or, according to Laboulbène, Micralymma), Obisium has no eflicient hairy covering

* While occupying the talle rented by Birmingham University at the Diolngical Station, Port Erin.
which serves to retain a coat of air for use during respiration under water, and it therefore probably has to rely upon the store of air contained within its tracheal system. Plateau* has pointed out that 46 genera and 80 species of tracheate Arthropods are known to inhabit the sea-shore and to be subjected to submersion by the water. In the greater number of these, he remarks, the power of living under such conditions is not due to their possessing any special mechanisms to enable them to do so, but to the general property those animals have of being able to resist asphyxiation for a prolonged period.

When in the living condition, Olisium maritimum is easily recognized by the olive-greenish colour of the body contrasted with the bright red-brown of the pedipalps. The species was described by Leach † as follows:-
" $C$. pedibus secundis articulo 2 cylindraceo, 3 ovato; basi attenuato 4 orato; digitis brecibus subeurratis.
"Long. corp. 2-2 $2 \frac{1}{2}$ lin.
"Habitat in Anglia occidentali inter rupes ad littora maris. Communicavit Dom. C. Prideaux.
"Color livido-fuscus, pedibus 4 anticis pallide ferrugineis; 8 posticis pallidis.
"Thorax antice nonmunquam ferrugineus."
It has been redescribed and excellently figured by PickardCambridge $\ddagger$; his description is given below :-
"Length slightly over one line.
"Cephalothorac and abdomen dark brown tinged with olive, and very glossy; palpi and falces red-brown; legs pale yellow-brownish tinged with olive. Cephalothorax slightly longer than broad, sides parallel, truncated in front in an oblique line on either side from the centre, where there is a slight but distinct shallow depression. Eyes rather large, very nearly of equal size; those of each pair are separated from the fore-margin and from each other by a diameter's interval. The hairs with which this species is furnished are long, fine, and simple. The palpi are long and strong; the bulb of the pincers is of a cylindrical-oval form ; the claws are strong and no more than (if even quite as much as) equal to the bulb in length and very slightly curved."

Pickard-Cambridge remarks that he has receired specimens from the Devonshire coast, where it was found under stones below highwater mark; and from Jersey, where it occurs in a similar situation. He further adds that it does not appear to be known on the Continent of Europe.

The present communication constitutes but the second recorded instance of the occurrence of this species in the British Isles since the time of Leach.

## THE ANNALS

## Magazine of natural history.

[SEVENTH SERIES.]

No. 87. MARCH 1905.
XXVII.—Natural History Notes from the R.I.II.S. 'Incestigator,' Capt. T. H. Heming, R.N. (retired), commanding.Scries III., No. 6. An Account of the new and some of the rarer Decapod Crustacea obtained during the Surveying Seasons 1901-190t. By A. C. MacGilchrist, M.A., MI.B., Ch.B., Capt. I.MI.S., Surgeou-Naturalist to the Survey.
During the season 1901-1902 the R.I.M.S. 'Investigator' was engaged in surveying parts of the Persian Gulf. Here most of the tramling and dredging operations were in comparatively shallow water, and a goodly collection of Brachyura was obtained. During the following two seasons the Tenasserim and Arakan coasts were being survered, and the collections were obtained mostly by deep-sea trawling en route between Bombay and the surver-ground on the outward and homewaid journeys.

Besides a short account of some of the rarer species and varieties obtained, three new species of Macrura, two new species of Anomura, together with one new genus and fire new species of Brachyura are here described.

> MACRURA.
> Fam. Peneidx.
> Peneus, Fabr. Peneus fissurus, Spence Bate.

Peneus fissurus, Spence Bate, 'Challenger,' rol. xxir. pt. i. 1858, p. 2 23.
This species is new to the Indian fauna. This year, strange Ann. \& Lrag. N. Hist. Ser. ̄̄. Vol. xv. 17
to sar, they were caught in abundance on two occasions in the Gulf of Martaban, 46 and 61 fathoms. In one haul fifteen males and seven females were obtained.

They agree in all details with Spence Bate's description. In the Indian varicty the rostrum is long, horizontal, slightly turncel up at the tip, and armed dorsally with 6 (sometimes 5) teeth; it is half (or more) the length of the carapace, longer in the female, where it is $1 \frac{1}{2}-2 \mathrm{~mm}$. more than half the length of the carapace, and is about twice the length of the eye.

The antennules of the female are shorter and more slender (both peduncles and flagella) than those of the male, and in consequence the antemal seale, which in the male is shorter than the antennular peduncle, is in the female considerably longer than the peduncle.

The antema is about $1 \frac{1}{2}$ times the length of the body (excluding the rostrum).

Two typical specimens of female and male give the following measurements :-

On analysis and comparison of about two dozen specimens the following sexual differences are apparent:-

Female.- Rostrum about twice the length of the eye and $1 \frac{1}{2}-2 \frac{1}{2} \mathrm{~mm}$. longer than half the length of the carapace: antcmular peduncle considerably shorter than the antennal scale; its larger flagellum very slightly longer than half the length of the carapace, and its smaller flagellum about two thirds the length of the larger.

Male.-Rostrum seldom twice the length of the eye and about half the length of the carapace: antenuular peduncle projects beyond the antennal scale; its smaller flagellum is very little shorter than the carapace, and the larger flagellum is a third as large again as the smaller.

Roughly speaking, the smaller flagellum of an adult male is about three times the length of that of a fomale. The small young male resembles the female as regards the relatise Jongths of antenaal scale and antennular peduncle and flagella.

The sixth abdominal segment is not twice the length of the fifth. Exopodites are not present on any of the legs. Epipodites are absent from the external maxillipeds as well as from the last three pairs of legs. There are no pleurobranchiæ on the last two thoracic segments.

## Benthesicymus, Spence Bate.

Benthesicymus armatus, sp. n.
In the general form, cut, and outline of rostrum and carapace this species resembles B. brusiliensis (Sp. Bate), but in the former there is a distinct hepatic spine as in B. moraius (S. I. Smith, Alb. Crust. 1886, p. 90).

With B. moratus this species is very closely allied. They differ only in the following points : $-B$. moratus has a sharp tooth posteriorly on the carina of the dorsum of the third, fourth, and filth abdominal segments; its third abdominal segment is carinated; its sixth abdominal segment is more than twice as long as high; its antennal scale is relatively narrower, and the rostrum-judging from the descriptionis not raised so much at the base as in this species.

The rostrum is long, reaching the tips of the eyes, and is dorsally armed with two small teeth. Between the crest of the rostrum and the cervical groove the median carina is very prominent; behind this it is distinct, though less prominent, to very neariy the postcrior margin of the carapace. The post-antennular angular projection of the carapace ends acutely anteriorly, and from this lobe a crest passes backwards in the direction of the hepatic spine. The branchiostegal spine, which is placed well back on the margin of the antero-lateral sinus, is larger than the hepatic spine and is well buttressed posteriorly. The carapace is deep, as in B. brasiliensis.

The eyes are in a bad state of prescrvation; they seem to be deficient in pigment.

The antennular peduncles reach about halfway along the antennal scales. The antennal scales are broad, being only about $2 \frac{1}{2}$ times as long as broad.

The last joint of the endopodite of the first maxilliped is $\frac{1}{5}-\frac{1}{6}$ as long as the penultimate joint, and the distal extremity of the exopodite suddenly ends in a fl:gellum. The second and third maxillipeds agree in all details with the description and plates of $B$. moratus (loc. cit.).

The branchial formula is typical of Benthesicymus Alcock, Desc. Cat. Ind. Deep-sea Crust. 1901, p. 43). Rudimentary exopodites are present on all the legs.

A small carina begins on the posterior two thirds of the fourth abdominal segment, and is continned back wards; on the sixth segment it is a rigid well-marked carina which terminates abruptly at the posterior margin. There is no tooth or spine on any of these segments. The third abdominal segment has neither carina nor spine. The sixth abdominal segment is barely twice as long as high. The telson has had its tip broken off.

Only one specimen (a female) has been obtained-trawled at Sta. 287 , Arabian Sea, 1500 fathoms-and it gives the following measurements:-

| Length of rostrum | $\mathrm{mm}_{10 \%}$ |
| :---: | :---: |
| ", carapace with rostrum | 61.6 |
| antermal scale |  |
| Breadth of | $12 \cdot 3$ |
| Length of sixth abdominal serment |  |
| " exdopodite of tail-fim | 23\% |
| , exopodite | 32.5 |
| Length from tip of rostrum to tip of $t$ |  |

This species is most closely connected with B. moratus, but can be distinguished from it by the points of difference already noted. From B. Tanneri and B. brasiliensis it can be distinguished by the presence of an hopatic spine and the absence of teeth on the carine of the abdominal segments. In B. Bartletti there is a long spine on the dorsum of the fifth abdominal segment. In B. altus the posterior margin of the sixth abdominal segment is elevated to form a transverse ridge.

Will be figured in an carly issue of the "Illustrations of the Zoology of R.I.M.S. 'Investigator.'"

> Gexvadas, Spence Bate.

Gennadas carinatus (?), S. I. Smith.
Benthesicymus carinatus, Smith, Alb. Crust. in Rep. U.S. Fish. Comm. 1882, p. 396 ; Alcock and Anderson, J. A. S. B. pt. ii. vol. lxiii. 1894, p. 147 ; Aleock, Desc. Cat. Ind. Deep-sea Crust. 1901, p. 46.
At Sta. 306, Arabian Sca, 930 fathoms, a large specimen (apparently the female of this species) was trawled. Previous to this there was only one specimen (a male, caught in the same locality, near the Laccadives, 902 fathoms) in the Indian Museum.

The following are the measurements of this female:-
mm .
Length of rostrum ..... 13
" carapace ..... 56
" abdomen ..... 88
" antennal scale ..... $30 \%$
Breadth of ..... 14.5
Length of sixth abdominal segment ..... 22
" telson ..... - $1 \cdot 4$
, imner uropod ..... 26
" outer ," ..... 29

It agrees in all details with descriptions of this species, except as regards the relative lengths of sixth abdominal segment, telson, and endopodites of tail-fan. The sixth abdominal segment is slightly shorter than the telson, and the telson is not quite so long as the endopodite of the tailfan.

A sternal tubercle is present in the female between the bases of the first pair of obdominal appendages. The crestlike dorsal carina on the third abdominal segment occurs only on the posterior two thirds.

The "thelycum" is peculiar. Between the bases of the fourth pair of legs a prominent central papilla stands. Towards this papilla a hairy process passes inwards and backwards from the base of each of the third pair of legs, and from the base of each of the fourth pair of legs a tongueshaped process projects inwards and backwards posterior to the papilla. The papilla thus stands in the centre between the tips of these four processes.

## Fam. Pandalidæ.

Heterocampus, A. M.-Edwards.

## Heterocarpus longirostris, sp. n .

At Sta. 310, Bay of Bengal, 960 fathoms, two males of this species were trawled. Of known species they are most closely allied to II. lavigatus, from which they difier only in the following characters :-

The rostrum is straighter and much longer (being about $1 \frac{3}{4}$ times the length of the carapace) and is multiserrate dorsally, the teeth being $\frac{1 V+9}{12 t o l t}$; the orbital spine is much larger, it is as large and projects quite as far as the branchiostegal spine; the blunt carina of the third abdominal somite is posteriorly acutely produced to a bluntish point, and is not merely strongly convex ; the sharp antemmar seate is shorter, it falls well short of the extremity of the second
joint of the antennular peduncle; the antennal scale is longer and narrower ; it is about $\frac{3}{3}$ length of the carapace, and its greatest breadth is very little more than $\frac{1}{4}$ its length.

| Length from tip of rostrum to tip of telson |  |  |  | $\mathrm{mm}_{14.5}$ |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | $5 \pm$ |
| ", | carapa |  |  | 31 |
| ", | fifth ab | om | som | $5 \cdot 8$ |
| " | sixth | , | " | 9 |

H. oryx (A. M.-Edwards) differs from this species in having spines on the third, fourth, and fifth abdominal segments and antemular flagella shorter than rostrum. In H. carinatus (S.I.Smith) the rostrum is shorter; antennular flagella are shorter than rostrum; third and fourth abdominal terga are produced posteriorly as spines.

This species has been figured, and will appear in "Illustrations of the Zoology of R.I.MI.S. 'Investigator,' " Crust. pt. xi., which is now being issued.

## Fam. Glyphocrangonidæ.

Glyphocrangon, A. M.-Edwards.
Glyphocrangon longirostris (?), Smith.
G'yphocrangon longirostris, Smith, 'Albatross,' Dec. Crust. 1886, p. 51.
Of this species, which is new to the Indian fauna, two specimens (male and female) were trawled at Sta. 326, off the Arakan coast, Bay of Bengal, 1100 fathoms. They are smaller than the specimens described by Smith, but agree with descriptions of this species except as regards the eyes. In the Indian specimens the eyes are decidedly smaller (length of carapace, including rostrum, about $8 \frac{1}{2}$ times the greatest diameter of the eyes) and are not of a dark purplish brown, but of a rashed-out purple or a tint resembling blackberry much diluted with cream.

|  | Male. | Female. |
| :---: | :---: | :---: |
| Length from tip of | $\begin{aligned} & \text { mu. } \\ & 64 \end{aligned}$ | $\min _{73}$ |
| Length of rostrum | 14.8 | 17 |
| ", carapace, excluding rostrum | 14 | 17 |
| Gratest diameter of eye | $3 \cdot 4$ | 4 |
| Length of antennal scale | 6.5 | $7 \cdot 6$ |
| Greatest breadth of antennal scale | 3.9 | $4 \cdot 4$ |
| Length of tlson | $12 \cdot 2$ | $14 \cdot 2$ |
| ", inner lamella of uropod | 9 | $10 \cdot 4$ |
| ," outer , ," | 8.5 | $9 \%$ |

The rostrum narrows from the antero lateral teeth formards; the antero-lateral teeth are large and prominent. The anterior part of the third carina is represented by 3 or 4 very small discrete tubercles on the hepatic area. There are a few scattered small low tubercles on the dorsum of the carapace between the carinæ. The large tubercles representing the first and second carimæ and the broad flat low tubercles of the abdomen have, like the other carine of the carapace, an eroded worm-eaten appearauce. A finc velvety pile covers the carapace and rostrum.

There are only nine branchis on either side-arthrobranchire (5) on ninth to thirtcenth somites, and pleurobranchire ( 4 ) on clesenth to fourteenth-cach series diminishing in size from behind forwards. From its reduced number of branchix, its relatively small eyes, which are somewhat deficient in pigment, and its dorsal and subdorsal carine of the carapace being broken up into lines of tubercles, this Indian species would come under Alcock's subgenus Plastocranyon (Alcock, Desc. Cat. Ind. Deepp-sea Crust. 1901, pp. 125 \& 133).

Of Indian species already known it is most nearly related to $G$. (Plastocranyon) cacescens, from which it differs in laving larger eyes; rostrum longer, slender throughout, acute, and with only two pairs of tecth; a less gramular surface; and only one tooth on the anterior part of the fourth carina. G. sicuria (Faxon) differs from this species in having the orbital spines smaller and less deflected outwards and the anterior part of the fourth carina divided by a notch into two prominences, of which the posterior is the more salient. In G. nobilis (A. M.-Edwards) the rostrum is relatively shorter and its modian dorsal keel does not run so far back; the 3 or 4 tubercles representing the auterior part of the second (subdorsal) carina are all produced to spinous points, and not merely the foremost of them; the tubercles on the abdomen are more numerous and discrete; the eyes have more pigment.

## Fam. Axiidæ.

## Calastacus, Faxon.

## Calastacus longispinis, McArdle.

Calastacus longispinis, McArdle, Ann. \& Mag. Nat. Hist. ser. 7 , whl. viii. Dec. 1901, p. 522 ; Illus. Zool. Invest., Crust. pl. 1vii. figs. 2, 2, 2 .
This species was described by Mr.trdle from a single specimen (female) dredged in the Arabian Sea at Sta. 279
in 300 fathoms. This season another female-a more complete and larger specimen (length of carapace and rostrum 16.6 mm ., of abdomen 97 mm .) - was trawled at Sta. 297 in the Gulf of Oman, 800-689 fathoms.

The median carina rumning backwards from the rostrum carries a large procurved acute spine in the anterior part of the gastric region. There is some variation in the number of spines on the rostrum and gastric region of the carapace. The margin of the rostrum has 4 or 5 spinclets in front of a basal spine on either side in its free portion, and on the continuation backwards of the rostral margin on each side the spines vary from 2 to 4 and may display a want of symmetry in number and position on the two sides of the same specimen. The spines lying between these and the median carina similarly vary from 2 to 3 in number.

The chelipeds were wating in MeArdle's specimen. In this specimen the larger is 26 mm . long, the hand alone measuring $9 \frac{1}{2} \mathrm{~mm}$. The ischium, merus (except distal part), and palm are much compressed. The lower borders of ischium, merus, and hand, and the upper borders of merus and carpus (distal parts), palm, and finger are spinose. These spincs are best developed on the merns; elsewhere (except at distal end of lower border of ischium) they are mere spinules. There is a small spine on the upper border of ischium near its distal end. The fingers are about as long as the palm and their prehensile colges are finely serrulate, the teeth pointing towards the tips of the fingers ; there is no hiatus left on closure. The smaller cheliped is 17 mm . long ; the inferior borders of ischium and merus are spinose; the fingers are very minutely and regularly sermate.

The second pair of ambulatory leqs are $2 \overline{2} \frac{1}{2} \mathrm{~mm}$. long; the third pair are rery slightly shorter; the fourth pair rescmble the second and third pairs, but are considerably shorter and more slender.

The telson has a fair-sized termiual spine with an upeurved tip.

## Iconamiopsis, Alcock.

Iconaxiopsis spmigera, sp. $\mathbf{n}$.
In size this species is intermediate between I. laccadirensis and $I$. andamanensis. The length of the rostrum is also intermediate ; it usually reaches to about the middle of the second joint of the antemular peduncle, but shows considerable variation in length, sometimes falling short of the end of the basal joint, sometimes reaching the distal end of the
second joint of the peduncle. The edges of the rostrum are microscopically serrulate, as in I. luccadlivensis. A median dorsal carina passes back from the rostrum for a short distance on the gastric region. On the average the rostrum is longer in the female. Little reliance can be placed on the length of the rostrum in determining this species.

The abdomen is longer than the carapace; the pleura of the second, third, and fourth abdominal segments are vertically produced and pointed. The carapace with the rostrum is about as long as the first five abdominal segments combined. The projecting pleura are very pliable, yet retain their smooth surface. In the female the appendages of the first abdominal segment are uniramons, slender and long, about $\frac{2}{3}$ the length of those of the second segment; in the male they appear to be wanting. They also seem to be wanting in the male of $I$. laccadivensis, but are present and well developed in the male of I. andamanensis. The telson has a small median posterior spine.

The eye-stalks are very short and the eyes have no pigment. All that is visible of the eyes is a fair-sized hemispherical white lobule on either side of the base of the rostrum.

The upper antemnular flagellum is about as long as the carapace (without the rostrum) measured in the mid-dorsal line, is slightly longer than the lower or inner flagellum and is two or more times its thickness.

Both "stylocerite" and "scaphocerite" are large; the former is the longer and almost reaches the end of the antennal peduncle.

The exopodite of the second maxilliped is much longer than the endopodite. The branchix agree with the typical formula of Iconaxiopsis as given by Alcock (Desc. Cat. Ind. Deep-sea Crust., Macr. 1901, p. 191), except that I was unable to find any rudimentary podobranch or arthrobrauch on the second maxilliped; they differ widely from the formula of Iconaxius (Spence Bate).

The chelipeds are massive, chelate, and subequal, the left (rarely the right) being the larger in both sexes. Both chelipeds are about the same length and are approximately as long as the abdomen; more than half this length is made up by the hand. The more massive cheliped has a longer, deeper, and more inflated palm than the other. In the former the palm is longer than the fingers, in the latter the fingers are longer than the palm. The upper border of the palm carries a row of (usually about 8) forwardly directed and prominent spines, which increase in size from behind
forwards and are easily visible to the naked eye. The palm, and especially the fingers, have numerous long hairs. On the upper margin of the free finger there is gencrally a spinule, best developed on the lager hand and in the male. A ridge, which is spinulose, runs along the outer margin of the broad lower burder of the palun and fixed finger. The stouter hand presents a hiatus when the fingers are closed ; into this space there projects from the basal end of the prehensile edge of the free finger a broad compressed tooth. The fixed finger is finely serrated in its distal two thirds, on the far side of a fair-sized conical tooth. In the smaller hand there is no hiatus; the fingers are curved inwards and excavated on their immer surface; the prehensile edge of the fixed finger is finely serrated. At the base of the fixed finger, at the distal end of the outer surface of the palm, a conical spine, simple or multicuspid, projects forwands.

In the female the larger hand is sometimes arrested in its development; for instance, in one specimen the large tooth on the free finger is in evidence, yet there is no hiatus, or, as in another specimen, not even this tooth is developed, and the larger hand exactly resembles the smaller in shape and form.

The lower borders of the ischium and merus of the chelipeds are spinose, and $1-3$ small low spinules are sometimes visible on the upper border of the merus at its distal end.

The first to fourth pairs of ambulatory legs are slender; the first pair are shorter than the second and third pairs, smooth and minutely chelate. The second and third pairs are about equal in length; their propodites are compressed and have along their posterior borders a row of small tufts of sete, which at first sight appear like fine spinules. The fourth pair of legs are about the same length as the first pair. The dactyli of the second, third, and fourth pairs of legs are short and subspathulate, and their distal edge is finely serrated, the anterior tooth being produced as a long curved hook.

The eggs are round, large (about $1 \cdot 6 \mathrm{~mm}$. in diameter), and few in number, about a dozen on the average.

At Sta. 310, Bay of Bengal, 960 fathoms, about a dozen specimens were trawled; of these five were femates, four of which were cgg-laden. An average-sized specimen gave the following measurements:-

This species differs from I. laccadivensis in being of larger size, upper border of palm spinose in all its extent, fingers more setose, rostrum shorter, pleura of second to fourth abdominal segments more pointed, eyes withont pigment, fixed finger in neither hand has two basal enlarged teeth separated by a notch. In I. andamanensis the rostrum is shorter and its edges smooth, eyes longer and more slender, pleura of second to fourth abdominal segments are not vertically produced or pointed, upper border of palm is not spinose, carapace with rostrum measured in the mid-dorsal line is merely a little longer than the first four abdominal segments combined.

This species will be figured in an carly issuc of "Illustrations of the Zoology of R.I.M.S. 'Investigator.' "

## ANOMURA.

## Fam. Pylochelidæ.

Cheiroplatea, Spence Bate.
Two specimens (male and female) of a new species of this genus were obtained at Sta. 327, off the Arakan coast, 419 fathoms. Each was housed in the mud-lined cavity of a piece of water-logged bamboo. They are closely allied to, but quite distinct from, C. cenobita (Spence Bate, Chall. Macr. Crust. pt. i. 1888, p. 12).

These specimens have been handed over to Major Alcock, Superintendent of the Indian Museum, by whom they will be described in his monograph on the Indian Paguridea, which will shortly be published.

This new species will be figured in "Illustrations of the Zoology of R.I.M.S. 'Investigator.' "

Fam. Lithodidæ.
Lithodes, Latrcille.

Lithodes Ayassizii, S. I. Smith.

Lithodes Ayassizii, S. I. Smith, Bull. Mus. Comp. Zool. x. 1882, p. 8, pl. i.; Henderson, Chall. Anom. p. 42.
A large female of this species, measuring with outspread legs about $2 \frac{1}{2}$ feet across, was taken at Sta. 301, northern part of the Arabian Sea, 1000 fathoms.
mm .
Lencth of carapace, excluding rostrum and poste- rior spines ..... 105
Lencth of rostrum with its spine ..... 22
" spines at base of rostrum ..... 18
, , larger spines of carapace ..... 14-28
", smaller ..... 3-i)
", larper pines on margin of carapace ..... 12-28
," smaller ..... 3-8
Gre:itest breadth of dorsal surface of carapace, ex- cluding spines ..... 93

The large spines on the carapace are less numerous than in any of the specimens described by Smith; in all other details this specimen agrees with Smith's description.

The gastric region is armed with three pairs of large spines, the cardiac region with two pairs, the intestinal with one pair, and the branchial region on either side with six large spines; the more posterior of these twelve pairs of spines on the dorsum of the carapace are longer than the anterior, and dotted in between these dorsal spines are about an equal number of smaller spines about $\frac{1}{3}$ the size of the large spines. On the margin of the carapace behind the large hepatic spine and the cervical suture are 9 large spines and $:-7$ intervening smaller spines about half (or less) the size of the larger. These marginal spines are not exactly symmetrical in place or size on the two sides. There is a small median spine in the sinus in the middle of the posterior border of the carapace.

This specimen differs very little from Smith's larger adult specimen. Like the latter it is nine tenths as broad as long, and the number of large spines differ only on the branchial regions and margin of carapace, where the difference in length of the larger and smaller spines may not have been so pronounced as in this specimen. The rostral spine, however, and the spines at its base are much longer in this specimen, being as long as the average large spine on the carapace, and resemble those of Smith's smaller adult specimen.

The abdomen has three large outstanding spines situated on the central plate which represents the fused first and second abdominal terga; the other spines on the abdumen are small in comparison with these three.

A figure will be given in the next issue of "Illustrations of the Zoology of R.I.M.S. 'Investigator.'"

# Fam. Galatheidæ. Muxidopsis, Whiteaves, Faxon. 

Munidopsis dasypus, Alcock.
Munidopsis dasymus, Alcock, Amn. \& Mag. Nat. Hist., April 1804, p. 329 ; Alcock, Descr. Cat. Ind. Deep-sea Crust., Macr. and Anom. 1901, p. 25² ; Illus. Zcol. Invest. pl. xiii. fig. 9.

Although numerous adult female specimens of this species have been caught in past years, the males have hitherto been represented by only two small young specimens. This season, at Sta. 331, east of Audamans, 569 fathoms, two adult males were obtained ; the extreme length of body of the larger male is 55 mm ., and the length of chelipeds is 69 mm .

The chelipeds of the male are (right and left approximately equally) enlarged in all joints and in all dimensions when compared with those of the female. The palms are much broadened and the fingers when closed leave at their base a fairly wide hiatus, into which a 3- or 4 -cusped tooth projects from the mobile finger.

The extreme length of body of the larger male caught prior to this season was 28 mm ., and its chelipeds were slender throughout, like those of the female, and without a hiatus at the base of the fingers.

There seem to be considerable and fairly frequent variations from the typical (and much the commonest number) 4 spines on the posterior border of the carapace. Variations found are $2,3,5$, and 7 .

A figure of the male will appear in "Illustrations of the Zoology of R.I.M.S.' 'Investigator.'"

Munidopsis Wardeni, Anderson, var. andamanica.
Munidopsis Wrardeni, Anderson, J. A. S. B. vol.1xr. pt.2, 1896, p. 99 ; Alcock, Desc. Cat. Ind. Deep-sea Crust., Macr. and Anom. 1901, p. 257 ; Illus. Zool. Invest., Crust. pl. Iv. fig. 1.

As mentioned by Alcock in his Descriptive Catalogue of Anomura, there are in the Indian Muscum two small specimens of M. Wardeni dredged off the Aidamans in 500 fathoms, and in these the abdominal terga have no spines. This season two similar but larger specimens (one an egg-laden adult female) were trawled at Sta. 3:3l, cast of the Andamans, in 569 fathoms, so that there would seem to be a distinct variety of species IV ardeni in that locality.

## 216 Capt. A. C. MacGilchrist on Decapod Crustacea

Measurements of egg-laden female :-

$$
\begin{aligned}
& \text { mim. } \\
& \text { Length of body from tip of rostrum to end of telson. . } 45 \\
& \text {, chelipeds.................................... } 5 \pm \text { } 5
\end{aligned}
$$

Besides the absence of spinules on the transverse carine of the second and third abdominal terga, the surface of the carapace generally is smoother and its ridges and rugre less prominent.

> Mumidopsis Milleri, Henderson, var.
> Munidopsis Milleri, Henderson, Chall. vol. xxsii., Anom. p. 155.

This specimen agrees with $M$. Goodridgei (Alcock and Anderson) and M. spinipes (sp. n. et sub descr.) in differing from all other Indian species in having the eyes fused ventrally, immovable, and furnished with no spine or spinule. This variety also comes from much the same depth and locality as M. Goodridgei : the former from 568 fathoms, west of Ceylon ; the latter from $1 \% 0$ fathoms, off the Travancore coast.

This specimen differs from Henderson's description of M. Milleri in the following points:-
(1) Gastric area armed with one pair of spines and three (instead of one) pairs of spinules. These spinules are arranged one pair behind the other and all lying on the circumference of an imaginary circle on the posterior half of the gastric region, thus:- the first pair situated behind the spines; the second pair behind these and wider apart, placed on the lateral mareins of the gastric region ; the third pair close together near the posterior margin of the gastric region.
(2) Rostrum is not spinulous, but subsquamiform.
(3) Instead of a spinule being present on the anterion border of the carapace behind the antenmal peduncle, the largest spine on the carapace is situated there.
(4.) Inner margin of palm is spinose and the upper surface is not smooth and glabrous, but has a few scattered tubereles and tufts of long silky hairs.
(5) There is a well-marked spinule in the centre of the triangular dilated area of the carapace, lying between the two divisions of the cervical groove.

This specimen differs from $M$. Goodridgei chiefly in:-
(1) Posterior border of carapace spinulose.
(2) An extra spine on the lateral border of the carapace.
(3) Three extra pairs of spinules on the gastric region and
a spine on either side of the carapace between the two divisions of the cervical groove.

Unfortunately only one specimen (a male) was obtained at Sta. 334, west of Ceylon, 568 fathoms.

Munidopsis spinipes, sp. n.
This species agrees with M. Goodridyei and M. Milleri, var. (above described), amongst Indian species in having the eyes absolutely immovable, yet furnished with neither spine nor spinule.

The carapace is conver, subquadrangular, about the same breadth in front and behind. A pair of large spines are situated anteriorly on the gastric region. There is no vestige of a spine or spinule on the cardiac region or posterior border of the carapace. The rostrum is short and styliform; towards its tip there is obseure microscopic serration on its lateral margins. The supra-antemnal spines are of good size. On the lateral border there are three large spines and one or two spinules, situated thus:-One spine at the antero-lateral angle, a sccond at the anterior angle of the triangular area lying between the two divisions of the cervical groore, and the third immediately behind the posterior division of the same groove; behind the second spine and lying with it between the two divisions of the cervical groove there may be one or two spinules, diminishing in size from before backwards.

The abdomen is smooth and has a few scattered hairs; the second tergum is transversely bicarinate, and the third transversely grooved. In the telson on either side between the two lateral plates there is a small calcareous patch, much the same as in M. ciliata.

The basal joint of the antennule has one spine and three spinules: the spine (large) on the outer side and two spinules on the inner side of the distal end of the joint; whilst the third spinule is on the far side of the globular swelling on the upper and outer surface of the basal joint. On the iuner edge of the merus of the external maxillipeds there are two large spines.

The chelipeds are subequal and much longer than (nearly a third as long again as) the fully extended body. The arm has three longitudinal rows of spines and four large terminal spincs ; the wrist has two rows of spines and four terminal spines; both edges of the outer surface of the palm are spinose. The fingers are not straight, but mect throughout their length; the fixed finger is fincly serrated, and a little
beyond its centre it has a projecting lobe which fits into a corresponding depression in the free finger. The free finger as finely dentate in its distal half or so ; its proximal half forms a projection, with its free margin coarsely dentate, which fits into a depression at the basal end of the fixed finger. There is no epipodite on any of the thoracic legs.

The ambulatory legs are long; the first pair are longer than the fully extended body. The merus of the first three pairs has a row of spines almost throughout the whole extent of its anterior border, and this is continued along the anterior border of the carpus as a row of spines, and not merely as a terminal spine ; their dactylus is hardly or only very slightly more than half the length of the propodite.

Three egg-laden females and one male were taken in the trawl at Sta. 310, Bay of Bengal, 960 fathoms. The male unfortunately had lost its chelipeds. The largest female gives the following measurements:-

$$
\begin{aligned}
& \text { Leugth of fully extended body, including rostrum . . } \quad 30 \cdot 6 \\
& \text { ", chelipeds.................................... . . . } 39 \\
& \text { " first pair of ambulatory legs............ } 31 \cdot 8
\end{aligned}
$$

This species is rery closely allied to M. Goodridyei, from which it differs manly in having no spines or spinules on the cardiac region ; chelipeds not very unequal, both of them much longer than the fully extended body, and both edges of the outer surface of the palm spinose; legs more spinose, the carpus having a row of two or more spines, and not merely a terminal spine on its anterior border ; the lateral border of the carapace with three spines and two spinules instead of two spines and one spinule.

This new species has been figured for the next issue of " Illustrations of the Zoology of R.I.M.S. 'Investigator." "

Munidopsis (Orophorhynchus) ciliatu, Wood-Mason.
Munitopsis ciliata, Wood-Mason, Ann. © Mac. Nat. Hist., Feb. 1891, p. 200 : Faxon, Mem. Mus. Comp. Zonl. xviii. 1895, 1. 84 : Alcock, Desc. Cat. Ind. Deep-sea Crust., Anom. p. 26 ; ; Llus. Zool. Invest., Crust. pl. xi. fig. 3.
Munidopsis brerimana, Henderson, Chall. Anom. p. 154, pl. xvii. fig. 1.
One male specimen (length of body, including rostrum, 43 mm . ; length of chelipeds $24 \frac{1}{2} \mathrm{~mm}$.) was caught at Sta. 326, Bay of Bengal, 1100 fathoms. It presented the following peculiarities:-Carapace and abdomen tomentose; lateral margins of carapace armed with only three spines, two only
being present between the two divisions of the cenvical grones and no spine at all at the extreme antero-lateral angle ol the carapace. In other respects this specimen agrees with descriptions of M. ciliata.

Last season at Sta. 310, Bay of Bengal, 960 fathoms, three small specimens of this species were caught in the same trawl: the smallest had the five typical spines on the lateral margins of the carapace; the other two had an extra sinall spine (making four in all) between the two divisions of the cervical groove. The number of spines on the lateral borders of the carapace of this species would thus seem to vary from three to six.

## Fam. Uroptychidæ.

## Uroptycius, Henderson.

Uroptychus glyphodactylus, sp. n.
Length of carapace, including rostrum, less than its greatest breadth. Carapace moderately convex from side to side, its surface and margins all smooth and glabrous except for a spime at each antero-lateral angle. Hardly any indication of regions. Rostrum has a broad base, but is exceedingly short, horizontal, and placed on a lower level than the summit of the carapace; in length it is considerably shorter than the eye-stalks. The pterygostomial region is very limited in extent, smooth, slightly inflated, and produced anteriorly as a well-marked acute spinule.

The eyes are of moderate size and, to the naked eye, of a uniformly brown colour; but under a lens they appear as a delicate dark brown network enclosing large pale facets. The eye-stalks are short, stout, and freely mobile.

The antennal acicle is very short and stunted, not more than $\frac{1}{3}$ the length of the antennal peduncle, the distal end of the penultimate joint of which the acicle does not reach. Like the rostrum it is broad at the base and rapidly tapers to a point. The flagellum is barely twice the length of the peduncle.

| Length of body, including rostrum. | Male. mm. 11 | Female mm. |
| :---: | :---: | :---: |
| ", ", excluding ,, ....... | $10 \frac{1}{4}$ |  |
| ", carapace, including rostrum | $4 \frac{3}{4}$ | $4 \frac{3}{4}$ |
| ", chelipeds : .................... | 26 | 22 |
| ,, second pair (longest) of ambula- |  |  |
| latory legs | 12 | 12 |
| Greatest breadth of carapace | $5{ }^{3}$ | $5{ }^{3}$ |
| Ann. de Mag. N. Hist. Ser. 7. Vol. xv. |  |  |

The chelipeds are long and smooth, except for a spinule on the dorsal margin of the ischinm at its distal extremity and 1-3 prominent spimules at the distal ends of both merus and carpus on their upper and inner aspects. There are a few tufts of hairs ( $2-5$ in each tuft) scattered sparingly on the joints, but mostly on the carpus; these tufts may escape notice unless looked for with a lens. On the fingers there are numerous lairs. The palm is very slightly shorter than the wrist and slightly dilated. The fingers are elegantly curved, forming at their base a wide hiatus, into which a conical tooth projects from the prehensile edge of each finger-that from the free finger being the larger and more distally placed. The summits of these two tecth are seen under a strong lens to be furnished with numerous spiniform cusps. In slightly more than their distal or apical third the closed fingr's leave no gap, the prehensile margins in that region being smooth or rery minutely scrrulate. The chelipeds are about five times the length of the carapace, including the rostrum.

The ambulatory legs are abont one third the stontness of the chelipeds; the first pair are slightly shorter than the second, which are about half the length of the chelipeds; the third pair are more than a dactylus shorter than the first or second pair. The legs are smooth, unarmed, and glabrous, except the dactyli and the posterior border of the propodites. These latter parts are well coated with hairs. The dactyli are strongly curved and long, being about the same length as the propodite, and their posterior border is finely toothed in its distal two thirds; the posterior border of the propodites is unarmed.

The abdomen is smooth and has hairs only on the margins of the pleura, telson, and caudal swimmerets. The telson is much shorter than (about lialf the length of) the caudal swimmerets.

The ova are large, about 1 mm . diameter, and comparatively few in number.

One male and an egg-laden female were trawled at Sta. 331, east of the Andamans, 569 fathoms. The female was found and preserved clinging to a species of Virgularia, the first pair of ambulatory legs fixed to the stem from below upwards, and the scond and third pairs clasping the stem from above downwards (or behind forwards).

In the female neither spines nor hairs are so well developed as in the male. For instance, the spine at the distal end of the upper margin of ischium of cheliped is hardly evident, and there are fewer and less prominent spines at
the distal ends of merus and carpas. The chelipeds of the female are much more slender and shorter than those of the male. Both chelipeds of the male are approximately equally enlarged (right palm possibly slightly more dilated than the left).

Of species hitherto described this one comes nearest Diptychus uncifer (A. M.-Elwards) and D. politus (Henlerson). The new species differs from the former in having a s!orter rostrum and still shorter antemal acicle; merus of cheliped smooth on its under surface, and no sharp tubercle on under surface of ischium; merus and carpus armed distally ; fingers entirely different. It differs from D. politus in the rostrum being much shorter and the acicle still more so; carapace broader than long; fingers different. This species can be at once distinguished by the form of the fingers, size of rostrum and antennal acicle, and the carapace being broader than long.

The telson and caudal swimmerets of the fomales of this genus are not so acutely flexed on the preceding segments or so closely applied to them as in the males.

Figures of both the male and female, the latter clinging to a species of Virgularia, will appear in "Illustrations of the Zoology of R.I.M.S. ' Investigator.' "'

## BRACHYURA.

## Oxyrhyecha. <br> Fam. Maiidæ. <br> Cyrtomaia Goodridgei, McArdle.

Cyrtomaia Goorlidyei, McArdle, Ann. \& Mag. Nat. Hist. ser. 7, vol. vi., Nor. 1900, p. 472 ; Ill. Zool. Invest. pl. lix. fige. $1,1 a, 1 b$, $\& 1 c$.
Of this species, described by McArdle from a single large male specimen, this season three more specimens-an adult and a young male and an egg-laden female-were obtained.

Dimorphism in the male.- The adult male was caught at Sta. 332, south-east of South Andaman Island, 279 fathoms. It is somewhat smaller than McArdle's specimen, but it presents this very striking and curious difference-its chelipeds are in all joints, but especially the distal extremities of the palms, very much enfarged and inflated. In the general arrangement of the spines on the chelipeils both specimens agree, and the gape (about $45^{\circ}$ ) is similar in both. The hiatus, however, left at the base of the fingers when closed is in the enlarged chelipeds much wider. The fingers
are stout at the base and rapidly taper towards the tips, and for this reason they appear relatively shorter than in Mcardle's specimen. both chelipeds of this new specimen are equally enlarged, and the relative lengths of their joints are maintained and correspond with those of the type specimen. Those ambulatory legs which happen to be present are not disproportionate in length or thickness when compared with the "type."

In the small male (length of carapace and rostrum 11 mm .) caught at Sta. 329, east of South Andaman Island, 378 fathoms, the chelipeds are slender and resemble a female's.

There is no evidence of the "type" having been attacked by parasites or other disease which might account for the chelipeds not being enlarged.

The relative size of the hand and palm in the "type," new male, and cerg-laden female respectively can be judged from the following measurements:-

|  | Type $\delta^{\circ}$. | New ס | Ovigerolls |
| :---: | :---: | :---: | :---: |
|  | mm. | $1 \mathrm{mm}$. | mm. |
| Length of carapace and rostrum | 3:3 | 29 | $21 \frac{1}{3}$ |
| , gastic spine | 13 | 11 | 7 |
| " branchial spine | $\bigcirc$ | ${ }^{\circ}$ | 4 |
| Greatest breadth | 32 | 28 | 21 |
| Length of chelipeds | 77 | 100 | $45^{\frac{1}{2}}$ |
| ," hand | $35 \frac{1}{2}$ | $46 \frac{1}{2}$ | 21 |
| Maximum and miniman lore palm. | $5 \frac{1}{2}-3_{2}^{1}$ | 11-4 | (2) $\frac{1}{2}-1 \frac{3}{4}$ |

Description of the fomale.-The egg-laden female was caught at Sta. 323, west of Cape Negrais, 463 fathoms. As in the male, on the strongly deflexed anterior portion of the carapace are well-raised granular ridges, three on either side extending from the large gastric spine to (1) the prominent postocular spine, (2) base of rostrum, and (3) base of concavity of orbital notch. The two immermost ridges which run to the base of the rostrum are thickly coated "ith long peg-shaped hairs. Rostral spines form a U-shaped interspace and the interantennulary spine descends in the same plane as the deflexed anterior portion of the carapace. There is merely a warty tubercle or prominence on a gramular mesial ridge midway between the two long gastric spines. Similarly a short warty transverse ridge represents the small intestinal spine.

The antero-external angle of the merus of the external maxillipeds is producel as a llat rounded projection armed with 3 or 4 acute spinules on its margin. Chelipeds and legs are armed with spines and setre.

In the female the chelipeds are only very slightly stouter than the first ambulatory legs. The fingers are very indistinctly toothed, the prehensile edyes being merely roughened ; they are not close-fitting. A small but well-marked acute spine is present at the base of the free finger on its dorsal aspect (present also in the male).

The sternum of the female has seven prominent spines, arranged as follows :-a spine at the base of each cheliped; another at the base of each of the first pair of ambulatory legs, on the margin of the concavity in which the eggs lie; a pair of spines placed transversely at the anterior edge of the same cavity; one (smaller) spine in the middle line between the last pair mentioned and the anterior border of the sternum. The whole space between the bases of the four pairs of legs is concave and occupied by the egrs, which are small and numerous.

The abdomen of the female is broad and carinate, except the posterior two thirds of the last segment ; it consists of seven distinct segments, of which the fifth and sisth are broadest. The surface is very granular and sparsely covered with longish hairs. A granular tuberele is present on the carina of the first scgment and a prominent acute spine on that of the sixth segment. The ambulatory legs diminish in length and girth from first to last; the last two pairs are very slender; the last pair in this egg-laden female are acutely flexed and carried dorsally.

Colour in life deep pink.
The female and the enlarged chelipeds of the male will be figured in an carly issue of "Illustrations of the Zoology of R.I.M.S. 'Investigator.' '"

## Fam. Parthenopidæ.

> Eumenonus, Edir.

Eumedonus gramulosus, sp.n.
Carapace depressed and sharply pentagonal. Bifurcation of rostrum at tip rery faint, occasionally absent, and then the bilobed nature of the rostrum can only be made out by the median longitudinal dorsal groove. The rostrum is transversely narrower and thicker (dorso-ventrally) than in E. zebra, where it is a broad thin lamina decply bifid at the tip. There are no coloured band-markings on the carapace. The surface of the body generally, including chelipeds and legs, is coarsely but evenly and regularly grauular. The regions of the carapace are well defined.

Chelipeds of female are no longer than the ambulatory legs, those of the male are much louger ; in both sexes they are more massive and armed with spines which are granular and not very acute. The most prominent of these spines is, as in E. zebra, that at the imner angle of the wrist. The palms of the male have no teeth on their upper border, those of the female have 2-1 teeth. The chelipeds are unequal in both sexes, the chicf difference being in the relative size of the palms; there is little difference in length, and that difference is due mainly to the palm of the right hand being longer as well as stouter than that of the left.

The ambulatory legs are only slightly compressed; the upper border of the merus is seldom cristate, but is granular (that of fourth pair being dentate) and ends in a distal tooth.

This species differs from E. zebra in having its surface coarsely granular ; no coloured bands on carapace; rostrum narrower, thicker, and only faintly notched at the tip; merus of legs not (or very seldom) strongly compressed or cristate.

Commensalism.-Fixedly adhering to the carapace and legs of a large male are a few tubicolous worms (Serpula) and one small patch of what scems to be Foraminifera Perforata (Polytrema).

At Sta. 291, 49-48 fathoms, two adult males, two ovigerous females, and several young specimens were got; at Sta. 296, 47 fathoms, an cgg-laden female and a young male were obtained: all are from the Persian Gulf, mud and sand bottom.

The largest specimens give the following measurements:-

| Length of cheliped | Origerous female. | Male. |
| :---: | :---: | :---: |
|  | $\mathrm{mm}_{11}$, | ${ }_{21}^{\mathrm{mm}}$. |
| ," carapace | 10 | 11.5 |
| ", third pair of ambulatory legs | 12 | 135 |
| Greatest breadth of carapace....... . | 10.8 | 11.5 |

This new species will be figured in an carly issue of " Illustrations of the Zoology of R.I.MI.S. 'Investigator.'"
Oxystoma.

Fam. Leucosiidæ.
Oreophores, Rüppell.
Oreophorus reticulatus, Adams and White.
Oreophorus reticulatus, Alcock, Carcin. Fauna Iud., Oxyst. p. 174 and reterences.
Of this rery variable species a single ovigerous female was
taken at Sta. 291, Persian Gulf, 49-48 fathoms. The carapace is 12 mm . long and 15 mm . broad; the length of the chelipeds is 15 mm . The eqgs are minute and numerous; they do not interfere with the tight elosing on the thorax of the lid-like abdomen.

This specimen presents the following peculiarities:-The surface and edge of the carapace, the ptergostomial regions, the external maxillipeds, the anterior margin of the thorax, and the chelipeds down to the very fingers are prettily ornamented in parts with an cucrusting growth of Foraminifera (Polytrema miniaceum, Mochius,' Mecresfauna von Mauritius'). These Forammifera form dark red irregular jagged processes on the grey-coloured carapace and other parts. The caverns are shallow; the second cavern has a wide open communication with the third, so wide that they look like one clongate cavern. The floors of the caverns and of the channel which bounds the intestinal region have bead-like granules scatiered over them. The tumid branchial regions are raised to a rugged peak, as in O. reticulatus, var. alcicornis, but the tip is not bifid. The outer surface of both fingers is smooth, without any trace of rows of pits.

Of seven Indian Museum specimens from off Ceylon, 34 fathoms, five have fingers exactly as in this specimen, the other two have well-marked rows of pits on the outer surface of the fingers. These Ccylon specimens are also encrusted, hut nothing like to the same extent, with the same species of Foraminilera; they have, however, three distinct and separate caverns on either side, and the branchial regions are tumid, but not raised and rugged.

## Ixoides cornutus, gen. et sp. n.

This genus agrees with Arcania and Ixa in having the hands much longer than broad, tapering from a swollea base, and the fingers opening in a nearly vertical plane, the tip of the dactylus movable through an are of about $60^{\circ}$. It is more closely allied to $I x a$, but it can be distinguished from either by the following diagnostic points:-The fingers are two thirds the length of the palm, or about half the combined lengths of wrist and palm; the sides of the carapace are produced into two stout, conical, horn-like processes, tapering from their base ; carapace is globular and its median regions are not pronouncedly demarcated by chamels or grooves; the merus of the external maxilliped has its outer edge cut away and bevelled, and this bevelled edge forms the imner wall of the afferent branchial canal; the front is moderately
prominent, projecting about as far as the salient edges of the afferent branchial canal.

The carapace of this species is globular, rhomboidal, not rery much broader than long, produced at the junction of the antero-lateral and postero-lateral borders into a stout horn-like process, which projects straight outwards, tapering steadily but very gradually until in its distal fifth it rapidly tapers off to a point; the proximal end of the lateral processes is not inflated or sausage-shaped, as in Ixa. Except for a deep sulcus on either side of the intestinal region, separating it from the branchitl regions, there is no pronounced grooving of the carapace ; in the adult faint indications of grooving can be made out, and in the young this grooving, although faint, is more discernible; much more distinct grooving can be seen in species of Arcania. The carapace in the young is covered with small vesiculous granules, which in the adult for the most part disappear, except in the anterior part of the carapace and at the bases of the processes. Between these vesiculous granules the surface is rough and finely granular. At either end of the posterior margin is a large, stout, papilliform process about a third of the length of the lateral processes. On the middle of the intestinal region there is a much smaller bullous projection. The front is bilobed and projects further forward than in Ixa. A very small bullous projection occurs on the summit of the antero-lateral convexity of the subhepatic region.

The orbits are emarginate on the dorso-lateral aspect in the region of the orbital sutures. The autennules do not fold so obliquely (by reason of the front of the carapace projecting more forwards) as in Ixa. The anteunal peduncles are small but distinct, and their flagella rudimentary.

The external maxillipeds, as in $I x a$, are partly sunken below the level of the edges of the buccal cavern, which is triangular, and the ischium is grooved along its inner border, but the merus is quite different and peculiar in its shape. The merus is grooved only in its basal fifth or so ; beyond this its outer edge is bevelled to such a degree that the upper surface in its distal two thirds is a mere ridge, and the bevelled outer edge dovetails with the margin of the efferent branchial canal and forms the inner wall of the afferent branchial channel. The inner borders of the exognaths are concave, their distal ends curving inwards and converging. The surface of the exognath is strongly convex and, like the raised outer border of the ischium, has a band of vesiculous grauules; its distal free margin is well fringed with hairs
and falls short of the raised anterior edge of the afferent branchial canal by a distance equal to about half the length of the merus.

The chelipeds are long, about twice the length of the carapace; the distal half of the hand is very slender; the fingers are about two thirds the length of the palm and are filiform.

The abdomen of the adult male (female unknown) consists of five pieces, the third, fourth, and fifth segments having coalesced; in the young specimen the sutures are still visible.

Three specimens (one large and two small males) were taken at Sta. 292 , Persian Gulf, mud bottom, 53 fathoms. The largest gave the following measurements :-

| Length of carapace | 29 |
| :---: | :---: |
| Breadth, including lateral processes | $2 \cdot 5$ |
| Length of lateral process | 14.5 |

Only one cheliped is present in the large specimen, and that one has had the tips of the fingers broken off; but one of the smaller specimens has a complete cheliped, which shows the following characters :-The cheliped is slightly more than twice the length of the carapace ; the fingers are well under half the length of the hand, are slightly hooked at the tip, and have their prehensile edges closely set with small microscopic jagged teeth, and at regular intervals a few larger and recurved teeth. This specimen gives the following measurements :-

$$
\begin{aligned}
& \text { mm. } \\
& \text { Length of cararace . . . . . . . . . . . . . . . . . . . . . . . . } 10 \\
& \text { " cheliped . . . . . . . . . . . . . . . . . . . . . . . . . } 20 \frac{1}{2} \\
& \text { ", palmı . . . . . . . . . . . . . . . . . . . . . . . . . . . } 5^{-\frac{1}{2}} 0 \\
& \text {, free finger . . . . . . . . . . . . . . . . . . . . . . . } 3 \cdot 8
\end{aligned}
$$

This species has been figured for "Illustrations of the Zoology of R.I.M.S. ' Investigator.'"

Fam. Dorippidæ.
Ethusa, Roux.
Ethusa hirsuta, McArdle.
Ethusa hirsuta, McArdle, Ann. \& Mag. Nat. Hist. ser. 7, vol. vi., Nov. 1900, p. 474 ; Illus. Zool. Invest., Crust. pl. lix. figs. 2, 2 a.
This species was described by MeArdle from an adult
female and a young male. This season two males were caught at Sta. 333, off the west coast of Ceylon, 400 fathoms.

Description of adult male. - The chelipeds are very unequal ; the right is in all joints and in all dimensions much larger than the left : the disparity in size is most marked in the palm, the right being many times larger than the left. The left cheliped resembles that of the female, is not enlarged, and is more slender than the first and second pairs of ambulatory legs; the right cheliped is more massive than these legs in all joints. The left cheliped does not reach as far as the fingers of the right, and the right cheliped is about three quarters the length of the first pair of ambulatory legs. The fingers meet only at their tips, and the prehensile edges are smooth and without a vestige of tecth, unless a smooth rounded lobe or bulging on the under surface of the free finger of the enlarged cheliped be excepted. The palm of the enlarged cheliped is large, broad, and inflated, and the fingers are short and stout.

|  | Male mm. |
| :---: | :---: |
| Length of carapace | 12 |
| Breadth | 12 |
| Length of smaller cheliped | $17 \frac{1}{2}$ |
| " larjer | 24 |
| " first ambulatory lega. | 35 |
| second " | 40 |

A noteworthy and what appears to be a specific character of $E$. hirsuta is the length of snont or spout formed by the efferent branchial channels. This spout, in either sex, extends forwards well between the bases of the antennules. In none of the males in the Muscum collection do the esternal orbital spines reach quite as far forwards as the rostral spines; they fall short, however, by very little. The imner pair of frontal teeth have a distinct tendency to be stouter and longer than the outer pair and to point slightly outwards.

The large male, which has the dimensions given above, will be figured in the next issue of "Illustrations of the Zoology of R.I.M.S. 'Investigator.' "

Cyclometora.
Fam. Xanthidæ.
Xanthodes, Dana.
Xanthodes cumatodes, sp. n.
Carapace roughly hexagonal; frontal and antero-lateral
borders forming together a strongly convex arch ; the posterolateral borders strongly convergent; the fronto-orbital border much more than half the greatest width of the carapace.

The anterior two thirds of the carapace are markedly areolated and peculiarly granular; the granules are beadlike and for the most part arranged in transverse rows, these rows occupying the tops of successive small ridges, which look like wavelets or ripples moving in a forward direction. Between these rows of granules and in the grooves defining the regions the carapace is smooth. The margins and sides of the carapace, along with the posterior third of the surface, are fairly uniformly studded with granules. No hairs on carapace. A sinuous groove marks off the fronto-orlital region; the gastric region is defined and divided into three subregions by similar deep groores, while a shallow longitudinal groove on cither side divides the lateral gastric subregions in two; the branchio-hepatic regions are divided by grooves into about four areas (a marginal, two dorsal, and an internal triangular one).

Front bilobed; the outer angle is not sharply marked off, and from it pass inwards two beaded ridges, which give the front the appearance of having a double edge. The outer angle is separated from the supraorbital margin by a well-marked notch. Antero-lateral border divided into four granular lobes or teeth. Between the first tooth and the external orbital angle there is a depression which allows, in a dorsal view, a small tubercle to be seen; this tubercle lies close to the first tooth of the antero-lateral border and lies in a line between it and the angle of the buccal cavity. The third lobe or tooth is largest, the first smallest; the second and fourth are about equal.

The three grooves of the orbital border are distinct. The inner and outer ends of the lower orbital margin end in teeth, the inner being much the larger. The basal antemnal joint is short and just reaches the front. A small dog's-carshaped flap projects from the eye-stalk on to the dorsal aspect of the cornea, and on this stands a tult of setr. There is a transverse row of granules on the front of the eye-stalk just internal to the cornea, the uppermost granule being usually enlarged and dentiform.

The anterior edge of the merus of the external maxilliped is almost transverse; there is a notch in it just external to the inner angle. The longitudinal ridges that define the efferent branchial canals are indistinct and do not reach the anterior boundary of the buccal cavern.

The chelipeds are not twice the length of the carapace;
merus not entirely hidden bencath the carapace; its outer surface has transverse rows of pearly granules and its upper border is spinulose in its distal part. Outer surface of wrist and palm furnished with pearly granules. The outer surface of the wrist is irregular, but gencrally shows a transverse groove at the distal end and a prominent tooth at the angle of the upper or inner border. The outer surface of the palm shows three parallel longitudinal furrows, as in X. Lamarckii, the pearly granules at the margins of the furrows being arranged in rows. The inner surface of the palm is smooth and polished. The fingers are pointed and blackish brown in spirits.

Upper margin of merus of ambulatory legs serrulate. The upper border of the carpus is peculiar ; it is furnished with a central and a subdistal hump, which make it saddleshaped. The upper border of the propodite is convex and, like that of the carpus, finely granular. A fine longitudinal gramular ridge runs along the outer surface of carpus and propodite. Dactylus is long and bristly and ends in a short horny spine.

Six females (four ovigerous) and one male were trawled at Sta. 292 , Persiau Gulf, mud bottom, 53 fathoms. The male, which is about the size of the largest female, gives length of carapace 8, length of cheliped 12, and greatest width 11.3 mm .

This species will be figured in an carly issuc of "Illustrations of the Zoology of R.I.M.S. 'Investigator.'" "

## Actumnus, Dana.

## Actumnus margarodes, sp. n.

Carapace subcircular, with concave postero-lateral borders, strougly arcolated and moderately convex ; it is not much broader than long. Frouto-orbital border is about two thirds the greatest width of the carapace. The central lobes of the front are prominent, somewhat depressed, and the central notch is shallow ; the outer angles of the front are not large, are well marked off from the central lobes, but are only marked off from the supraorbital angles by a shallow groove. The antero-lateral border is cut into three teeth exclusive of the outer orbital angle.

The main areolation on the anterior half of the carapace is $-U$ - shaped, and is surmounted by a band ( $1-2$ deep) of sharp erystalline granules; the lateral arms are continued outwards and backwards in a gentle curve towards the third or last tooth of the antero-lateral border. A short
transverse band of these granules also lies on the branchial region on either side in a line between the posterior teeth of the antero-lateral borders. A similar band marks the anterior cardiac region, and the imner halves of the supraorbital margins are likewise furnished with these granules. A few of these crystalline granules also occur on the upper aspect of the wrist and palm of both the laryer and smaller chelipeds.

The posterior half of the carapace has a dense short furry coating, as also have thorax, abdomen, chelipeds to bases of fingers, and the exposed surfaces of the legs.

The supra-orbital margin has a noteh just internal to the outer angle. The outer orbital angle is dentiform and similar to the teeth of the antero-lateral border. Just below the outer angle is an angular notch. The basal antennal joint just reaches the front ; the orbital hiatus is not closed.

The chelipeds are unequal ; upper border of arm is serrulate; inner angle of wrist is sharp, its exposed surface having a few sharp crystalline granules, as also has the outer surface of the palm. Margins of legs are fringed with long hairs.

Ouly one male specimen was obtained, at Sta. 292, Persian Gulf, 53 fathoms. Length of carapace 6 mm ., the greatest width 7.5 mm . A figure of this specimen will be given in "Illustrations of the Zoology of R.I.M.S. 'Investigator.'"

## Fam. Cancridæ.

Trichopeltarium, A. M.-Edwards.

## Trichopeltarium ovale, Anderson.

Trichopeltarium ovaie, Anderson, J. A. S. B. vol. 1xv. pt. 2, p. 103 ; Illus. Zool. Invest., Crust. pl. xxv. figs. 4, 4a; Alcock, Carc. Faun. Ind. no. 4, Brach. Cyclom. pt. 2, 1899, p. 96.
This species was described by Anderson from a single specimen (a female) caught off the west coast of Ceylon. This season another female was caught at Sta. 323, west of Cape Negrais, 463 fathoms, and also a male at Sta. 32: , east of South Audaman Island, 378 fathoms.

Description of male.-It is smaller than any of the females in the Museum collection. As in the female, a very prominent and procurved lateral epibranchial spine is present on either side; it is about the same size as the frontal prongs. The three frontal spines are about the same length; in the specimens available the central spine is in the male very
slightly shorter and in the females very slightly longer than the lateral. The measurements of the male are as follows :-

|  |  |
| :---: | :---: |
|  |  |
|  |  |
|  |  |
|  |  |
|  |  |
|  |  |

The cornere are very deficient in pigment and are represented by small, hemispherical, pinkish-tinged patches placed obliquely (posterior aspect) on the summit of the loner, slender, but rigid eye-stalks, which are frecly movable in the horizontal plane. These corneal patches scem to be very easily detached, for they are absent from about half the number of eye-stalks examined.

The chelipeds are very unequal in the male; all joints of the larger cheliped (the right) are cnlarged in all dimensions. The merus is huge, and is not curved to correspond with the inflated pterygostomial region; it is straight, and fully half the joint projects free beyond the margin of the carapace. The most marked difference between the two chelipeds is in the hands. The palm of the larger cheliped is inflated and its immer surface is practically smooth, being coated merely by very minute vesiculous granules. The fingers are markedly different in the two chelipeds. Instead of being long, slender, acute, curved, slightly excavated on the inner surface, and of equal length (tips coinciding), as in the smaller cheliped and in those of the female, the fingers of the larger cheliped are straight, stout, and relatively short. The fixed finger is relatively very short and inflated: the free finger is deep and vertically compressed; its free border is highly arched and is armed with spines, tubercles, and hairs almost to the very tip. The free finger is $21 \frac{1}{2} \mathrm{~mm}$. long and overlaps in parrot-beak fashion the short fixed finger, which is only 13 mm . long. The fingers, when approximated, are not close-fitting, and each has 6 or 7 coarse tecth. The smaller cheliped is stouter than the legs.

Both sternum and abdomen are much narrower than in the female. At the level of the interspace between the bases of the first and second pairs of ambulatory legs the breadth of the abdomen is about $\frac{1}{3}$ breadth of sternum in the same transverse linc. The abdomen is seven-jointed and covered with coarse hairs ; the first two segments bear spines just as in the female; the other segments, however, have neither
spines, tubercles, nor granules, but are all smooth like the last segment of that of the female. The vasa efferentia perforate the coxopodites of the last pair of legs, the openings being of fair size.

The male has been figured for "Illustrations of the Zoology of R.I.M.S. ' Investigator.'"

Fam. Corystidæ.<br>Gomeza, Gray.

Gomeza distincta, de Haan, var.
Corystes (Oeidea) distincta, de IIaan, Faun. Jap., Crust. 1850, p. 45, pl. xiii. fig. 2.
Gomean, Gray, Zool. Misc. p. 39.
The only difference between this variety and the type described by de Haan is that the spine of the infraorbital margin of this one is much shorter than (in fact reaches only about a third of the way along) the supraorbital spine.

It should also be noted that of the ten marginal spines on either side of the carapace the four anterior ones, although decidedly larger and with broader bases than the following spines, are not by any means so much larger in comparison with these latter as the figure given by de Haan represents them. In this case it requires more than a superficial examination or glance to make out that the four anterior spines are larger ; in de Haan's figure these four are enormous compared with the following spines.

Only one specimen (a male), 8 mm . long and 5.5 mm . broad, was caught, and unfortunately its chelipeds and legs are wanting. It was trawled at Sta. 292, Persian Gulf, 53 fathoms.

This genus is new to the Indian fauna.

> Catometopa.

Fam. Gonoplacidæ.
Ceratorlax, Stimpson.
Ceratoplax gramulosa, sp. n.
Length of carapace is three quarters its greatest breadth. Front is a little less than one third its greatest breadth, deflexed, decidedly arched, and deeply notehed.

Not only is the palm on its outer surface coverel with very prominent vesiculous granules, but the surface and sides of the carapace as well, except a transversely oval patch
about half the breadth of the carapace stretching across the intestinal region, where the surface of the carapace is densely pitted. Regions of carapace are fairly well marked out. Surface of carapace, chelipeds, and legs sparsely covered with hairs and the margins are more thickly coated and with coarser hairs, which latter have a tendency to be arranged in rows, as, for instance, on the propodite of the first ambulatory leg.

|  | Male mm. |
| :---: | :---: |
| Breadth of carapace | 16 |
| Length | 12 |
| Breadth of front | 5 |
| Length of third pair | 27 |

Orbits are widest internally, corresponding with the eycpeduncles, which are conical, with the broad base internal. Eyes are fairly well pigmented, little, if at all, deficient in pigment. The antero-superior margin of the eye-peduncle is acute, covered with longish hairs, and lies in line with a similarly hair-clad transverse ridge at the upper borders of the deflexed front, this ridge marking the angle of flexion of the front on the carapace proper.

The basal joint of the antenna reaches the level of the lower border of the orbit and falls short of reaching the posterior border of the deffexed front merely by the breadth of the slender second antemnal joint. The second antennal joint projects by more than half its length beyond the front and supports the third joint (which is more than half the length of the second joint) and a moderately long flagellum.

The buccal cavern gradually widens from behind forwards ; longitudinal ridges of endostome evanescent; ischium of external maxillipeds a little longer than broad and with a longitudinal sulcus; merus transverse, with the anteroexternal angle produced and rounded, and with a notch at the antero-internal angle from which the next joint springs.

Chelipeds are shorter than legs; the imer angle of the wrist is produced to form a very distinct tooth or spine, and on the upper margin of the merus is a subdistal tooth, very well developed and prominent and more acute than that on wrist. Ambulatory legs are compressed, except the dactyli, which are styliform; the third pair, which are the longest, are $2 \frac{1}{4}$ times the length of the carapace, and the fourth or last pair are much smaller than the others. Projecting distally from the postero-superior margins of the coxopodites of the ambulatory legs are peculiar tortoise-foot-like processes, the distal free margin of each process being toothed
or pectinate and reaching a fair distance along the ischiopodite. They are most easily seen when the legs are drawn away from the sides of the carapace, for these small processes, which are rigidly fixed to the coxopodites, then project dorsally-free and solitary. When the legs are drawn up towards the sides of the carapace each process lies in close contact with the posterior surface of the basipodite and ischiopodite of its own leg, and gives support to these joints in forward movements (legs being fixed) of the body of the crab. The largest process is that of the third or largest pair of legs. The process arises from the coxopodite immediately above and continuous with the usual angular projection of the coxopodite in the region of the hiuge-joint between coxo- and basipodite.

The first two abdominal segments are very short: the first is sery broad, but does not reach the bases of the last pair of legs; it is wedged firmly in between the posterior border of the carapace and the thorax.

Colour in life dark muddy grey.
One specimen (a male of the above dimensions) was canght at Sta. 328, Gulf of Martaban, 61 fathoms.

This new species differs in the following points from the hitherto described species:-In C. ciliata the outer surface of palm is smooth and polished ; carapace punctate and regions not distinguishable; third pair of ambulatory legs shorter. In C. arcuata basal antemal joint shorter; upper margin of palm not cristate; outer surface of palm smooth and naked; general configuration of carapace different. In C. hispida a thicker coating of hairs, and hairs coarser; carapace pitted; front broader; eyes deficient in pigment. In C. (?) lavis carapace smooth and shiny; front wider; wrist and outer surface of palm smooth. With C. villosa and C'. leptocheles (Zehnter) this new species has very little in common.
C. gramulosa will be figured in the next issue of "Illustrations of the Zoology of R.I.M.S. 'Investigator.'"

## Fam. Palicidæ.

## Palicus, Philippi.

Palicus investigatoris, Alcock, var.
I'alicus investigatoris, Alcock, Carc. Faun. Ind., no. 6, Brach. Catom. p. 455.

This variety differs from the " type" only in the following characters:-
(1) There is a small but distinct fissure towards the inner end of the lower border of the orbit.

Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.
(2) The four tecth of the front are not equally acute; the miner two are long and acute, but the outer, although projecting well forward, are broad, blunt, and rounded at the end.
(3) The tecth on the posterior border resemble more those of $P$. serripes in being broad and blunt.
(1) Between the sharp little tubereles on the arcolx of the carapace the surface is not smooth, but is densely and finely granular.

Only a male ( 9 mm . long and 11 mm . broad) was obtained, Sta. 291, Persian Gulf, 49-18 fathoms.

## Fam. Ptenoplacidæ.

## Prenoplax, Alcock and Anderson.

## Ptenoplax dentata, sp. n.

Carapace very flat and depressed, transversely oval, and its antero-lateral borders dentate. Surface very fincly granular bencath a short furry coating; front and antero-lateral borders with much longer hairs. Front proper is extremely narrow, about ${ }_{1}^{1+4}$ greatest breadth of carepace ; in length about $\frac{1}{9}$ greatest breadth of carapace, deflexed, aud with its tip frce, horizontal, and tapering to a point-not expanded and bilobed as in P. notopus. Orbital and frontal borders together are slightly more than $\frac{1}{3}$ greatest breadth of carapace; antero-lateral border is long, convex, and armed with 3 teeth (besides the supraorbital tooth); postero-lateral border is convex and smooth; posterior border proper is straight and raised. Regions of carapace are fairly well defined. The branchial regions are much depressed and less inflated than in $P$. notopus. The two transrerse sutures so conspicuous and sharply defined in $P$. notopus are not prescnt, but the blunt, convex, transverse ridges in which the sutures exist in $P$. notopus are here quite as prominent and similarly situated, the anterior passing across the carapace between the pemultimate teeth of the antero-lateral borders.

The side-walls of the carapace are also finely granular and meet the dorsal surface almost at right angles. The pterygostomial regions are deeply grooved and the stemum is pentagonal, as in $\boldsymbol{P}$. notopus, their surface being finely granular.

Orbits are incomplete; their inferior border is formed by the basal joint of the antennule, that of the antenna, and the infraorbital spine. A vertical antero-posterior plane through the supraorbital spine passes between the basal joint of the antena and the infraorbital spine. Eye-stalks are short and conical ; the cornea (small and hemispherical) is placed obliquely (looking outwards) on the summit of the eye-stalk. The basal joint of the antemule is hugely inflated, globular, frecly mobile, and with a finely granular surface; second and third joints cylindrical and comparatively slender, fold transverscly on the swollen basal joint. The antenne arise on the same level with and between antennule and infraorbital spinc, and the flagellum is about half the length of the carapace.

The eyes, second joint of antennule, and the iuflated basal antennule joint all extend outwards and reach about the same distance. This is a specific character of this new species. In P. notopus the eyes extend outwards as far as the infraorbital spine, and the second antenuule joint also extends well beyond the inflated basal joint and reaches the basal joint of the antenna.

Epistome is linear ; buccal cavity is wider in front than behind. Efferent branchial channels are well defined, patulous, and produced anteriorly. External maxillipeds are subpediform and leave uncovered the greater part of the underlying mouth-parts; the palp arises from the apex of the small oval merus; merus and ischium have a fincly granular surface.

Chelipeds are unsymmetrical in the male; both are about the same length, but the right is thicker in all its joints. Both lands are also of equal length, but they differ in the relative lengths of palm and fingers; the right hand has not ouly a stouter but also a slightly longer palm than the left, but the latter makes up the difference by having longer fingers. The length of the hand, which equals that of the renaining part of the cheliped minus the wrist, is very slightly less than the length of the carapace. The smaller palm is compressed, the larger inflated. Fingers are longer than palm, compressed, acute, curved, and slightly excavated on the imer surface. The fingers of the smaller hand are
indi-tinct'r serrated, those of the larer are coarsely dentatesurface of chelipeds (except fingers) is tincly granular and the margius of arm and wrist are fringed with long hairs.

The first three pairs of ambulatory legs are slender, compressed, have a finely gramular surface as far as the merus (inclusive), and end in sabre shaped dactyli; carpopodites and propodites are fringed with long hairs. The fourth or last pair of legs are small, subdorsal in position, and arise near the middle line of the body.

The abdomen of the male consists of five separate segments -third, fourth, and fifth being fused-and has a finely granular surface. The abdomen corresponds very closely with that of $P$. notopus, eren to the crescentic ridge on the sixth segment. Its breadth opposite the penultimate pair of legs is about a third of the breadth of the stermum at the same point. The genital ducts open as in P. notopus.

Only a single specimen, and of the above dimensions, was obtained, trawled at Sta. 33: , south-east of South Andaman Island, 279 fathoms.

This specimen is of special interest, as it adds a second species to the hitherto solitary species- $P$. notopus-of the family Ptenoplacila of the Indian fauna. The two species resemble each other closely, but differ markedly in the following points:-The sculpture and outline of the front and carapace, especially the antero-lateral borders and the transverse sutures of the carapace ; the orbits; the relative lengths of the eyes, the second and basal joints of the antenuules.

Has been figured for " Hllustrations of the Zoology of R.I.M.S. 'Investigator.' "
XXVIII. - Natural History Notes from the R.I.M.S. 'Investigator,' Capt. T. H. Heming, R.N. (retired), commanding-Scrics III., No. 8. On a new Gemus of Teleostean Fish closely allied to Chiasmodus. By A. C. MacGilchirist, M.A., M.B., Ch.B., Capt. I.M.S., Surgeon-Naturalist to the Marine Survey.

Suborder Percesoces (Boulenger). Fam. Chiasmodontide, Gill. Dysalotus Alcocki, gen. ct sp. n.

$$
\text { B. 7. D. VIll. } 27 . \text { A. 27. P. 11. V. I, } 5 .
$$

The body is clongate and compressed; its height contained
nearly eight times in the total length without the caudal. The head is large, low, and long, contaned about $3 \frac{1}{2}$ times in the same standard length.

The snout is very long and depressed, about 3 times the diameter of the eyc and more than $\frac{1}{3}$ the length of the head. The eyes are lateral, wide apart, small, and deep-set. The interorbital space is more than twice the diameter of the eye, nearly flat from side to side, and traversed by two anteriorly converging ridges which enclose a V-shaped space. The nostrils are slightly nearer to the eye than to the tip of the snont.

The mouth is very deeply cleft, reaching beyond the cyes. The lower jaw projects beyond the upper; no barbel. The mucous system of the head is well developed.

The body is naked except the posterior half or so, which is furnished with minute spiny scales arranged for the most part in rows parallel to the lateral line ; the spinules have a backward inclination.

The lateral line is single, minterrupted, very broad, and conspicuous; it runs from the upper angle of the gillopening to the base of the caudal, curved slightly dowhwards, and contains a row of about 41 distinct pores.

Two separate dorsal fins: the first begins slightly posterior to the vertical through the base of the pectoral, and contains 8 slender spines; the second begins a couple of millimetres behind the first, is much the longer, and contains 27 rays. The anal is equal, opposite and similar to the second dorsal. Caudal symmetrically forked. Pectorals long (about half the length of the head) and slender, in position nearer the ventral than the dorsal line; all rays branched. Ventrals ( $\mathrm{I}, 5$ ) short (not so long as snout), inserted below the pectorals, but comected only by ligament with the clavicular arch.

Vent about 8 mm . in front of where the anal fin begins. No anal papilla; small urogenital papilla behind the vent.

The jaws are distensible, with four series of setiform teeth, similar in both jaws; those of the imner rows longest; all movable and turned inwards. No vomerine teeth; a single row of small teeth-depressible backwards-on each palatine. Tongue free. Gill-openings very wide, with membranes joined only quite anteriorly. Seven branchiostegals. Gills four; last gill-cleft a foramen mercly. Branchial arches weak and gill-rakers represented by small fixed and fairly numerous teeth similar to those of the month. Pseudobranchize are present.

An air-bladder is present, but without an open duct. 'The
pyloric ceeca were densely matted together and entangled with parasitic worms; there were about nine caca. Beside these the hepatic duct opened into the gut. Vertebre 39 (15 abdominal and 24 caudal). Abdomen extends well behind the rent into the tail. The stomach is elongate, cecal in shape, and empty; its inner surface presented large, coarse, longitudinal ruga. Liver small.

## Two strange Structures.

1. An anobliterated yolk-sac (?).-Lying free in the peritoneal cavity to the right of the stomach and extending from the liver anteriorly to near the vent was an elongate bladder with a shiny pearly external coating of peritoncum. Its posterior end was free and broad; its anterior end was narrow and formed a long neck which was distinctly traced up to the large vessels of the liver; from these vessels a large bianch descended along the neck, and broke up into smaller branches in the bladder-wall.
2. A rectal cacum.-From the region of the pyloric exca there descended a cecum which entered the anterior or rentral surface of the rectum about 2 mm . above the vent. In the posterior part of its course it was in intimate connexion with the ventral aspect of the rectum. Its anterior relatious could not be ascertained with certainty, as during the unravelling of the pyloric ceca the anterior extremity of the cæcum got broken.

The colour in life was violet-black.
A single specimen, about $9 \frac{1}{2}$ inches long, was caught in the trawl at Sta. 315, Bay of Bengal, near the Andamans, 705 fathoms. It has been figured and will appear in the next issue of the "Illustrations of the Zooiogy of the R.I.M.S. 'Investigator.' "

Named after Major Alcock, F.R.S., Superintendent of the Indian Museum, in gratitude for the guidance and help he has invariably given to the Surgeon-Naturalist.
XXIX.-List of a small Collcetion of Odonata (Dragonflies) from Ceylon, collected by Mr. E. E'rnest Green, with Notes on the G'enus Zygonidia and its Allies, and Descriptions of new Species of Zygonidia, Kirb., and Onychothemis, Brauer, from Ceylon and Tonkin. By W. F. Kirby, F.L.S., F.E.S., de.

I mate lately received, through Mr. W. J. Lucas, an assortment of dragonflies collected by Mr. E. Ernest Green, chiefly
at Kandy, in 1900 and 1901; and although there is but one new species among them, it seems worth while to give a complete list, because the specimens are all ticketed with dates and localities. A single ant-lion, not yet determinen, but probably belonging to the genus Creayris, ILas., wis among the dragontlies.

Libellulidæ.-Libeletretye.

1. Tholymis tillarga, Fabr.

Kandy, Dec. 1900. (2 specimens.)
2. Pantala fluvescens, Fabr.

Caught at light, Peradeniya, Oct. 11, 1900 ; also at Kandy and Yatigantata, Nov. 1900. (3 specimens.)
3. Neurothemis tullia, Dru.

Kandy, Nov. and Dec. 1900. (2 specimens.)
4. Trithemis aurora, Burm.

Peradeniya, June 1900; Kandy, Dec. 190). (4specimens.)
5. Brachythemis contaminata, Fabr.

Kandy, Dec. 1900. (18 specimens.)
6. Macrodiplas vittata, Kirb.

Ramisaram Island, S. India. (1 specimen.)
7. Zygonidia ceylonica, Kirb., sp.n. (infrà).

Kandy, Feb. 1901.
8. Orthetrum sabina, Dru.

Peradeniya, June 1900; Kandy, Nov. and Dec. 1900. (4 specimens.)
9. Orthetrum pruinosum, Burm.

Kandy, Nov. and Dec. 1900. (4 specimens.)
10. Diplacodes trivialis, Ramb.

Kandy, Nov. 1900 ; Peradeniya and Jaffera, March 1901. ( 4 spechnens.)
11. Acisoma panorpoides, Ramb.

Kandy, 1900. (1 specimen.)

Agrionidæ.-A Griontive.
12. Neurobasis chinensis, Linn.

IIangam, Nov. 1900; Kandy, Fel. 1901. (4 specimens.)
13. Vestalis apicalis, Selys.

Matale, March 1900 ; Kandy, Nov. and Dec. 1900. (13 specimens.)
14. Micromerus finalis, Selys.

Kandy, Nov. 1900. (2 specimens.)-
Agrionidæ. Cexnagronive.
15. Platysticta tropica, Selys.
(Kandy ?), Nov. 1900. (1 specimen.)
16. Disparoneura ceesia, Selys.

Kandy, Nov. and Dec. 1900. (5 specimens.)
17. Micronympha senegalensis, Ramb.

Ramisaram Isfand, S. India. (1 specimen.)
18. Nicronympha aurora, Brauer.

Kandy, Dec. 1900. (1 specimen.)
19. Archibasis ceylonica, Kirb.

Jaffera, March 1901. (2 specimens.)
Notes on the Genus Zygonidia, Kirb., and its Allies.
Since I founded this genus (Ann. \& Mag. Nat. Hist. (7) v. pp. 533, 540, 1900) for Zygoniaia insignis, Kirb., from Hainan, several additional notes have been published. Mr. Laidlaw has described another species from Malacca, and the Natural History Museum has received four specimens from Tonkin and Ceylon, referable to undescribed species.

Krüger has discussed Zygony.x (Neurocera) ida, Selys, and considers Zygonyx ida and Z. iris too close to form more than separate sections in one genus (Stett. ent. Zeit. Ixiii. pp. 110-113, 1902).

In Pseudomacromia torrida, Kirb., the front ridge of the middle and hind femora is armed with numerous short spines,
directed towards the knce, and becoming rather longer towarls; the extremity of the femora, where they are fullowed by three or four long sete. The front carina of the front femora and the hind carina of the hind femora are also armed with extremely fine teeth.

The genus Pseudomacromia must therefore be placed in the immediate neighbourhood of Zygonidia, though the claws are not bifid, but dentated ${ }^{*}$.

I add here a list of the described species of Zygonidia, with descriptions of new species from Ceylon and Tonkin.

## Genus Zygonidia, Kirb.

Zygonidia, Kirb. Ann. \& Mag. Nat. Hist. (7) v. pp. 532, 540 (June 1900).

## 1. Zygonidia insignis, Kirb.

Zygonidia insignis, Kirb. l. c. pp. 533, 540, pl. sii. fig. 1 (June 1900). Hab. Hainan.
2. Zygonidia malayana, Laidlaw.

Zygonidia malayena, Laidlaw, Proc. Zool. Soc. Lond. 1902, i. pp. 73-75, tig. 11 (femur).
Hab. Kwala Aring, Malay Peninsula.
3. Zygonidia ceylonica, Kirb., sp. n.

ठ.-Long. corp. 57 mm . ; exp. al. ant. 102 mm ., lat. 9 mm. , long. pter. $2 \frac{1}{2} \mathrm{~mm}$. ; lat. al. post. 14 mm. , long. pter. 3 mm .
f.-Long. corp. 55 mm ; exp. al. ant. 105 mm ., lat. $11 \mathrm{~mm} .$, long. pter. 3 mm .; lat. al. post. 16 mm. , long. pter. 3 mm .

Male.-Head : upper part rich purple, sides of frons and genæ yellow; the rest of the face dull bluish black, except the mentum, which is shining black, borderel on the sides and front with yellow. Occiput black. Thorax and abdomen black above, with three yellowish spots on the median line between the wings; a strong carima, narrowly lined with yellowish, on segments $2-8$ of the abdomen. Pleura greenish blue, with broad yellow sutures; first two abdominal segments with a small yellow spot on each side. L"gi hlackish; femora with numerous short spines directed towards

[^32]the knee, probably followed in perfect specimens by 3 or 4 long cilia.

Abdomen slightly dilated at base; terminal appendages about as long as the eighth segment, which is shorter than the seventh, which again is shorter than the sisth. Upper appendages of usual form, waved and pointed; lower one nearly as long, broad at base, with the narrowed extremity turned upward; below the basal half is a large oval excrescence, preceded by a tubercle on the under surface of the eighth segment.

Wings clear hyaline; pterostigmata, as in all the genus, dark brown; front wings with 16 antenodal cross-nervures, the last discontinuous on the left-hand side, and 9-11 postnodals in the upper space, the postnodals rarely coinciding with those in the lower; cells beyond the pterostigma single; nodal sector undulating, arched strongly downwards at the extremity; a single row of cells between the nodal and subnodal sectors, except close to the margin; two crossnervures in the lower basal cell; triangle with one crossnervure above the middle, and followed by three rows of cells, increasing towards the margin ; subtriangular space consisting of 3 cells ; upper sector of the triangle rising from its apex, the lower rising considerably beneath it.

Hind wings with 11 antenodals and 11 postnodals; 1 nervure in the lower basal cell; base of triangle distinctly nearer the base of the wing than the arculus, and its point not extending to the level of the triangle of the fore wings. Triangle traversed, followed by one row of 3 cells and one or two rows of 2 increasing; sectors of the triangle rising from a point.

All the wings rather pointed, owing to their rapid contraction beyond the point where the sectors of the arculus reach the margin. Membranule small, especially on the fore wings, greyish brown, whitish towards the base.

Hemale.-Head: metallic green above; face and mentum as in the male, but more broadly and brightly yellow on the sides, and no yellow in front of the mentum. Eyes brown above, broadly reddish in front and at the sides, which is only faintly visible in the male.
'l'horax and abdomen black above, with 3 yellow median spots between the wings, and a slender yellow line on the carina from the second to the seventh segment of the abdomen. Pleura with 3 broad yellow bands, separated by 2 green ones; first and second segments of abdomen with the tramsverse carine yellow, a large yellow trapezoidal lateral
spot on the first and a long one on the second. Denticulation of femora rather finer than in the male.

Wings of a slightly yellowish hyaline; front wings with 16 antenodal nervures on the right side, the last discontinuous; 15 continuous ones on the left side; 11 postuodal.s on the right side in the upper space and 10 on the left; membranule whitish, very narrow; otherwise as in the nale. Hind wings with 11 antenodals and 10 or 11 postnodals; otherwise as in the male.

Hab. Kandy, Feb. 1901 (E. E. Green). Two specimens, ot and 9 .
Distinct from all the other species before me by the comparatively short pterostigma.
4. Zygonidia єnea, Kirb., sp. n.

ठ.-Long. corp. 54 mm . ; exp. al. ant. 97 mm ., lat. $10 \mathrm{~mm} .$, long. pter. 4 mm ; lat. al. post. 12 mm. , loug. pter. $3 \frac{1}{4} \mathrm{~mm}$.
q.-Long. corp. 57 mm . ; exp. al. ant. 110 mm ., lat. $11 \mathrm{~mm} .$, long. pter. 5 mm . ; lat. al. post. 15 mm. , long. pter. $4 \frac{1}{2} \mathrm{~mm}$.

Male.-Head purple above; frontal ocellus very conspicuous, yellow; face black, with a slight greenish tinge; the gena, the lower border of the frons, and the rhinarium yellowish; mentum broadly bordered with yellow at the sides.

Thorax brown above, dull yellowish on the sides, with two broad bronzy-green bands in front above and two on the pleura on each side. Abdomen bronzy black above, 3 interalary spots on thorax, and narrow yellow lines on abdominal carine, as in $Z$. ceylonica. Base of abdomen slightly inflated, dull yellow on the sides as far as the base of the fourth segment, crossed by broad black lines at the end of each segment, and a narrower one on the carina of the second segment. Legs black, the femoral denticulation very tine.

Wings of a slightly yellowish hyaline, and very slightly clouded at the tips; front wings with 16 antenodal crossnervures, the last discontinuous, the fifth on the right-hand side V -shaped, and 9 or 10 postnodals; the postnodals in the upper space rarely corresponding with those in the lower; cells beyond the pterostigma single; nodal sector undulating, arched strongly downward at the extremity; a single row of cells between the nodal and subnodal sectors, except irregularly towards the margin; two cross-nervures in the lower
basal cell, triangle with a cross-nervure just above the middle, and followed by three rows of cells, only increasing towards the margin, subtriangular space consisting of 3 cells; upper sector of the triangle rising from its extremity, the latter separated, and rising considerably below.

Hind wings with 11-12 antenodal and 10-11 postnodal cross-nervures ; two cross-nervures in the lower basal cell; triangle with 1 or 2 cross-nervures, its base somewhat nearer the base of the wing than the arculus, and its aper not extending to the level of the triangle of the front wings. 'J'riangle fillowed by one row of 3 cells, and several rows of 2 increasing; sectors rising from a point.

Membranules smoky grey, that of the hind wings followed by a smoky shade over the cells which immediately border it.

Female.-Upper part of the head bronzy green, with the conspicuous yellow frontal ocellus; face from the lower part of the frons to the rhinarium inclusive yellow, except for very narrow black sutures; below this to the mentum bronzy black, except a yellow spot at the base of the mandibles; mentum black in the middle, with the sides broadly yellow. Thorax and pleura nearly as in the male, but the pleura brighter yellow, and marked with 3 black depressed spots: 2 higher ones just in front of each of the metallic-green bands, and 1 lower one a little behind the first pleural green band. Interalary spots dark yellow, much larger than in the male, and a much broader stripe of the same colour, expanded on the front segments, rumning over the carina of the abdomen to the end of the seventh segment; the slightly inflated basal segments are mostly of the same colour, which is continued by a row of long lateral spots, gradually shortening, as far as the seventh segment. Legs bronzy black, femoria finely denticulated, and with terminal seta; front femora pale beneath.

Wings rather deeper-coloured than in the male, and more clouded towards the tips. Fore wings with $16-17$ antenodal cross-nervures, the last discontinuons, and $10-11$ postnodais. Nodal sector more arched towards the extrensity than in the male, the space between the nodal and subnodal sectors thus widening considerably just before the extremity, where it again contracts. Triangle crossed by one or two crossnervures; lower basal cell with two cross-nervures; membranule small, brown ; other characters as in the male.

Hind wings with 11 antenodal and 11 or 12 postnodal nervures. One cross-nervure only in the lower basal cell ; triangle traversed by 1 nervure; membranule brown, as are
also the immediately adjacent cells; other characters as in the male.

Hab. 'Tonkin (Fruhstorfer).
Allied to Z.insignis, of which the female is unknown. The male is very distinct from any other described species of Zygomidia by possessing two cross-nervures in the lower basal cell of the hind wings. The female has but one, as usual.

## Genus Neurocena, Kirb.

Neurocena, Kirb. Amn. \& Mag. Nat. Hist. (7) v. p. 541 (1900).

## Neurocena ida, Hagen.

Zygony.x ida, Hagen \& De Selys, \&c. (cf. Kirb. l. c.).
Newrocena idu, Kǐrb. l. c.; Laildaw, Proc. Zool. Soc. Lond. 1902, i. p. 72, pl. v. fig. l.

Another specimen ( ठ) from Province Wellesley is now in tle Natural History Museum.

## Genus Onychothemis, Brauer.

Onychothemis, Brauer, Yerh. zool.-bot. Ges. Wien, xviii. pp. 170, 365, 732 (1868) ; Kirl. Trans. Zool. Soc. Lond. xii. pp. 258, 284 (1889).
Two species only have been described in this remarkable genus:-O. abnormis, Brawer (ll.cc.), from the Philippines, and O. testacen, Laidlaw (P. Z. S. 1902, i. pp. 75, 76, tig. 12 (leg), and pl. v. fig. 2), from Malacea. Libellulio hova, Ramb., from Madagascar, doubtfully referred to Onychothemis by Brauer and Kirby, is now referred by Karsch and Calvert to Pseudomacromia, Karsch (nec Kirb.).

I have just discovered a specimen of a third and extremely handsome species in the Natural History Museum which resembles Zygonidia in neuration (last antenodal discontinuous, triangle of the fore wings placed beyond the level of that of the hind wings, base of triangle of hind wings nearer the base of wings than the arculus), but differs from it entirely by the great spines on the femora and tibia and the simple claws. There is no carina on the fourth segment.

## Onychothemis notabilis, Kirb., sp. n.

Long. corp. 54 mm. ; exp. al. ant. 100 mm ., lat. 11 mm , long. pter. $4 \frac{1}{2} \mathrm{~mm}$. ; lat. al. post. 13 mm ., long. pter. 4 mm .

Female.-Head metallic green above, with the ocelli conspicuously yellow; face black, lower border of trons, upper border of nasus, and rhinarium dull yellow, also gene and
base of mandibles; mentum black, sides yellow; occiput black, occipital triangle and two spots behind each eye yellow ; a yellow transverse band on back of collar; thorax and abdomen black, thorax with a conspicuons median line; pleura greenish bronzy, with three rather narrow oblique yellow stripes, the first shortest and followed below by a curved yellow stripe above the middle coxæ; interalary spaces spotted with yellow; abdomen very slightly inflated at base, with no longitudinal line aloove, but with a yellow spot in front of the second segment, the sutures from the second to the fifth segments and the carina of the third segment narrowly yellow; a row of large lateral spots, divided by the carine, from the third to the seventh segments, a small one below the carina on the eighth, and an additional spot, bisected by a dark line, on eack side of the median carina on segments 6 and 7. Legs black; front femora denticulated beneath, and with 1 long spine towards the extremity on the inner side ; tibia setose bencath, with 5 long spines diminishing in length on the outer side, and 2 or 3 shorter ones on the inner; middle and hind femora with rows of spines, increasing in length towards the extremity and longest on the hind femora; middle tibiæ with 4 and hind tibie with 5 pairs of long oblique spines, not quite symmetrical. Claws large, curved, not toothed or bifid.

Wings yellowish hyaline, slightly smoky at the tips, neuration black; pterostigma very dark reddish brown; front wings with 16 or 17 antenodal cross-nervures, the last not continuous, and 10-11 postnodal cross-nervures; nodal sector much waved, one row of cells between the nodal and subnodal sectors, increasing towards the margin ; sectors of the arculus rising at two thirds of its length; one crossnervure in the lower basal cell; triangle traversed slightly above the middle, placed beyond the level of that of the hind wings, regular, and followed by 3 rows of posttriangular cells; subtriangular space consisting of 3 cells. Membranule of moderate size, grey, as also on the hind wings.

Hind wings with 10 antenodal and 11-12 postnodal crossnervures; triangle open (the base placed nearer the base of the wing than the arculus), followed by one row of 3 cells and then by rows of 2 or 3 increasing ; sectors of the triangle rising in a point at its lower angle.

Ilab. Tonkin (Fruhstorfer).
A single female specimen of this handsome species.
XXX.-Description of a new Species of Palophus (Phasmidie) from West Africa. By W. F. Kirby, F.L.S., F.E.S.
Labee Phasmida are probably numerous in Africa, but they are at present usually received only as single unpaired specimens, and are very little known. Herewith I describe a male specimen lately received from West Africa, allied to Palophus centaurus of Westwood, and associate with it, with some slight hesitation, a specimen which has been in the Natural History Museum for some years, included in the serics of P. centaurus, from which it appears to be distinct, though the differences are less salient than in the male.

## Palophus Alldridgei, sp. n.

## Dimensions ( $\mathbf{\sigma}^{\circ}$ ).

Male.-Almost uniform wood-brown. Head with a double laminated crest, slightly oblique, trifid above, and slightly dentated in frout; behind it is a short, pointel, conical tuherele on each side, and several smaller pointed tubereles. Median
segment trifid, with the middle section pointed in front, as in $P$. centaurus ${ }^{6}$. Front femora and tibiee hardly curved, the others more or less so; four hinder tibie with an oval lamella near the extremity above, which is rudimentary on the front tibia; middle femora with a large single or double laminated and rectangular projection near the base; righthand tibia with a small tooth on the under surface just beyond the lamella. Tegmina brown, blackish in the middle, with ill-defined white spaces towards the base, and near the middle of the costa. Coriaceous portion of the wings wood-brown, with blackish, occasionally interrupted, lines on the longitudinal nervures. Membranous portion of the wing hyaline, nearly the apical third (from about one third of the length on the costal side to about two fifths of the length of the hind margin) reticulated with light brown, and large partly connected white spots and markings, irregularly arranged in rows. The inner oblique border of this tessellated area becomes indistinct and irregular, fading into the hyaline pertion of the wing.

Hab. Bonthe, Sherbro, W. C. Africa.
This specimen was found by Mr. T. J. Alldridge (after whom I have named it at his request) in his bedroom at Bonthe, and kindly presented by him to the Museum. The male is allied to Palophus centaurus, Westw., but longer, more slender, and with variegated wings. From P. hippotaurus, Karsch (which, judging from the discription, I refer to Buctrodudema, Stål), which it resembles in wing-coloration, it differs by its unarmed thorax. The males of $P$. centaurus in the Museum have the tips of the wings only slightly clouded, much less so than in the insect described and figured by Brongniart (Nouv. Arch. Mus. Paris, (3) iii. p. 197, pl. viii., 1892), which has the outer subcostal area of the wings tessellated, and perhaps belongs neither to $P$. centaurus nor to $P$. Alldridgei. The exact locality of Brongniart's specimen is not stated.

Female.-Light greyish brown; head with an erect double lamellated crest, tridentate above and slightly dentated in front; behind its base are two rows of raised spines on each side, the front and inner ones longest. Mesothorax with a short black dash on each side about the middle, but asymmetrical. Abdomen with a slight double lamella on the fifth segment. Front femora with a row of undulated lanelle above and two near the middle on the outcr side; tibire with three more distinct double ones on the outer and two smaller ones on the inner side (tarsi wanting). Middle and hind femora and tibire much arched, the femora with a large lamella above and below near the base; tibia with several
small and irregular lamellæ. Tegmina wood-brown, more strongly humped than in the male, blackish on the hump, aml whitish towards the base. Wings as in the male, except that the whole membranous area is brown, tessellated with irregular rows of large subhyaline spots.

Mab. W. Africa (Swanzy).
In the true $P$. centaurus the wings of the female are blackish, with the subhyaline spots much more numerous, much smaller, less confluent, and more regular.
XXXI.—Descriptions of new West-African Frogs of the Genera Petropedetes and Bulua. By G. A. Boulenger, F.R.S.

A Few years ago \% I had occasion to offer some remarks on the genus Petropedetes, Reichenow, and pointel out the differential characters of the three species then known, all three from West Africa, viz. P. cameronensis, Reichen., the type of the genus, with the toes half-webbed and the tympanum half the diameter of the eye; P. Johnstoni, Blgr., with a mere rudiment of web between the toes, and the tympanum hali the diameter of the eye ; and P. (Tympanoceros) Newtoni, Bocage, with a mere rudiment of web between the toes and with a very large tympanum, remarkable for the presence, in the male, of a dermal appendage projecting from its centre. I have since received examples of two new species, differing from those previously described in the fully webbed toes, and for these I propose the names $P$. natator and $P$. palmipes; the former is from Sierra Leone, the latter from South Cameroon. The genus Bulua was described by me quite recently $\dagger$ for a new frog from South Cameroon, B. ventrimarmorata; a second species, from the same country, may now be added, and is here described as $B$. albiventris.

## Petropedetes natator.

Tongue rather feebly notched behind, without conical papilla. Vomerine teeth in two small groups close together behind the level of the choanæ. Head strongly depressed, a little broader than long; snout roundel, shorter than the

[^33]orbit, with obtuse canthi and nearly vertical, concave lores; interorbital space as broad as the upper eyelid; tympanum moderately distinct, barely half the diameter of the eye. Fingers moderately elongate, much depressed, with large, cordiform terminal disks; first finger shorter than second; toes rather short, broadly webbed to the disks, which are a little smaller than those of the fingers; subarticular and inner metatarsal tubercles feebly prominent. The tibio-tarsal articulation reaches to between the eye and the tip of the snout; tibia half as long as head and body; foot about two fifths length of head and body. Upper parts closely covered with round granules intermixed with elongate warts; lower parts smooth. Male with internal vocal sacs, a sharp tooth-like process at the symphysial extremity of each ramus of the mandible, and a more or less distinct large oval gland on the lower side of the thigh. Olive-brown above, with round darker spots on the body and cross-bars on the limbs; lower parts brown.

From snout to vent 55 mm .
Several specimens from Sierra Leone, presented to the British Museum by Major F. Smith, R.A.M.C.

Major Smith informs me the specimens were taken from a mountain torrent in a rocky bed at an altitude of 800 feet. 'The frog is a powerful swimmer and jumper, and clings to rocks, roots of trees, \&c. by means of its digital disks.

## Petropedetes palmipes.

Tongue rather feebly notched behind, with a conical papilla in the middle. Vomerine teeth in two short transverse or oblique series behind the level of the choanæ. Head strongly depressed, as long as broad; snout obtusely pointed, a little shorter than the orbit, with obtuse canthi and very oblique concave lores; interorbital space narrower than the upper eyelid; tympanum rather indistinct, about one third the diameter of the eye. Fingers rather elongate, with large, cordiform terminal disks; first finger shorter than second; toes moderately elongate, webbed to the disks, which are it little smaller than those of the fingers; subarticular and inner metatarsal tubereles feebly prominent. The tibio-tarsal articulation reaches beyond the tip of the snout; tibia three fifths to two thirds as long as head and body; foot nearly half as long as head and body. Skin shagreened or glandular above; a more or less distinct glandular line along the middle of the head and body; lower parts smooth. Male with internal vocal sacs and a well-defined large oval gland
on the lower side of the thigh. Dark olive above, spotted or marbled with darker and lighter ; limbs with broad dark and narrow light cross-bars ; lower parts dirty white.

From snout to vent 53 mm .
Several specimens from Efulen, South Cameroon, collected by Mr. G. L. Bates.

## Bulua albiventris.

Series of vomerine teeth nearly straight, widely saparated in the middle, and not extending outwards beyond the choane. Head much depressed, broader than long; snout short, rounded; no canthus rostralis; eye moderate ; interorbital region about once and a half as broad as the upper eyelid; tympanum very indistinct, its diameter about half that of the eye. Fingers short, with slightly swollen tips, first and second equal; toes moderate, the tips dilated into small disks; subarticular and inner metatarsal tubercles feebly prominent. The tibio-tarsal articulation reaches the posterior border of the eye. Skin smooth. Dark brown or black above, with small round white spots on the sides; hind limb with light spots or marblings; lower parts white, throat sometimes marbled with brown.

From snout to vent 25 mm .
Three specimens from Efulen, South Cameroon, collected by Mr. G. L. Bates.
XXXII.-Remarks on Mr. N. Rosén's List of the Snalies in the Zoological Nuseums of Lund and Malmö. By G. A. Boulenger, F.R.S.

The naming of snakes from descriptions is a difficult task for beginners, who should not be encouraged to publish descriptions of so-called new species, which only go to swell the synonymy. There is no book in existence by the aid of which the difficulties connected with the study of the dentition can be entirely overcome, and I doubt whether such a book will ever be written. I have done my best to supply a guide to the determination of snakes (' Catalogue of Suakes, in the British Museum,' 1893-1896), and that it does not work in the hands of some students, as evidenced by Mr. Rosén's paper published in the last number of these 'Annals,' I deeply regret.

Of the new species described the types of only two are figured with sufficient clearness to be recognizable, and both these prove to be identical with quite common species. Coluber fascirtus of Rosén is based on a Drymobius Boddeertio, var. Roppii, Gthr., and the snake from Java named after Prof. Lilljeborg, and for which a new genus is proposed under the preoccupied name Anisodon, is a Psammodynastes gulverulentus. Probably many of the other determinations, if they were looked into by a competent herpetologist, would be found to be unreliable.

There is, however, one case in which the identification cannot be questioned, and that is the common Chrysopelea ornata figured on pl. xi. fig. 1. Of this snake I have examined the vertebre in several specimens, in spirit or prepared as skeletons, and I cannot find more than a keek under the posterior precaudal vertebre, which are figured by Mr. Rosén as with strongly developed hypapophyses (p. 171, fig. $d$ ). As this snake is quite common in collections, and the necessary examination can easily be made on a spiritspecimen, I would invite any reader who may be interested in this matter to verify my statement.
XXXIII.-Crustacea Copopoda new to Science from Devon and Cormuall. By Canon A. M. Norman, F.R.S., and Thomas scott, LL.D., F.L.S.
We are preparing for publication a catalogue of the Crustacea of Devon and Cornwall. In that catalogue, while both authors are concerned in the whole, Dr. Ecott will more especially undertake the part which relates to the frec-living Copepoda, while the rest of the Crustacea will be chiefly treated of by Canon Noman. We have thought it desirable to publish the following preliminary descriptions of some new species of minute Copepoda. They were collected by Canon Norman during visits to the Devon and Comish coasts in the years $1875,1884,1889,1903$, and 1904 .

## Genus Stenifelia, Boeck, 1864.

Stenhelia pygmea, sp.n.
Description of the female.-Body moderately stout and tapering slightly towards the posterior end. The specimen from which the description is prepared was only : 36 mm .
(about $\frac{1}{7 \pi}$ of an inch) in length and carriel a single moderately large ovisac; the forehead is proluced into a small but distinct rostrum.

Antemules short, eight-jointed, first and second joints large, the fourth to the seventh very small; the third and last are subequal and also small, but rather larger than the intermediate joints, as in the formula-

Proportional lengths of the joints ................. 20.20.9.4.3.3.4.11 Numbers of the joints from proximal end of antennule. $\begin{array}{llllllll}1 & 2 & 3 & 4 & 5 & 6 & 7 & 8\end{array}$

Outer ramus of posterior antennæ small and triarticulate. Mandible-palp moderately stout, with two small branches. Second maxillipeds not very robust, and armed with slender elongated terminal claws.

Inner branches of first pair of legs slender and considerably longer than the outer branches, the first joint only slightly longer than the last, while the middle joint is rather more than half the length of the first; the outer branches reach to near the end of the middle joint of the imer branches. Second, third, and fourth legsalso slender; the outer branches of the fourth legs are only slightly longer than the inner. Fifth pair of legs small : primary joint broadly subtriangular, but with the apex truncated and bearing three scter of nearly equal length and one about the same length as the others near the distal end of the inner margin. Secondary branch moderately narrow, subcylindrical, tapering slightly towards the distal extremity; breadth scarcely equal to half the length; apex slightly produced in the middle to form the base for a slender seta; a slender seta springs from near the distal end of the inner margin, and there are also about four seta on the outer margin, the two lower ones being stouter than the others.

Furcal joints very short.
IHub. Dredged near Eddystone Lighthouse, Aug. 31st, 1901 ; apparently not common. No males observed.

The small size of the female, the peculiar structure of antemules, of the first pair of legs, and the form and armature of the last pair distinguish this from any other known to us. This species has recently been observed in dredged material from the Firth of Forth.

## Stenhelia simulans, sp. n.

Description of the female.-The female of this species has a general resemblance to Stenkelia ima, G. S. Brady. Antemules eight-jointed, moderately stout, scarcely so clongated
as those of S. ima ; the first four joints are together equal to about twice the entire length of the last four ; first, second, and fourth juints subequal, but the second rather longer than the other two; third about half the length of the second and nearly equal to the last ; the fifth, sixth, and seventh small, as shown in the formula-

Proportional lengths of the joints.。 20.26 .12.20.6.7.9.14
Numbers of the joints. ............ $\begin{array}{lllllllll}1 & 2 & 3 & 4 & 5 & 6 & 7 & 8\end{array}$
Antenne nearly as in S. ima; outer ramus small, triarticulate.

Second maxillipeds moderately stout; second joint about 1 wice as long as broad, having a series of minute bristles arranged horizontally on the lateral aspect and near the middle, and with a small but distinct seta on the inner margin and towards the distal end; terminal claw moderately slender.

First pair of natatory legs moderately slender; the outer branches reach to about the end of the first joint of the inner, and the exterior spines are slender and elongated; each of the three joints fringed with minute cilia on the outer margin; first and second joints with also a number of delicate cilia on the inner margin; inner branches have the first joint rather longer than the entire length of the second and third, while the end joint is fully twice the length of the middle one. The last pair are somewhat similar to those of S. ima, but the secondary joints are proportionally broader, being about half as broad as long; there is also a slight difference in the armature.

IIab. Dredged near Chequer Buoy in the neighbourhood of Plymouth, Aug. 14th, 1903; apparently not common.

The more important differences between the species just described and S. ima, which it resembles, are found in the proportional lengths of the joints of the antemules, the greater proportional leugth of the outer branches of the first pair of legs, and in the secondary joints of the fifth pair being proportionally broader.

## Stenkelia neglecta, sp. n.

Description of the female.-This species is moderately slender and about 8 mm . in length. Rostrum moderately elongated and slender. The antennules resemble those of Stenhelia ima in length and number of joints, but the lengths of the joints differ as shown by the formula-

Outer ramus of the antenne small and apparently triatienlate, but the middle articulation is minute and somewhat indistinct.

First pair of legs slender; inner branches moderately elongated; first joint about as long as the entire outer branch, while the second and third are about half the length of the first, the middle joint being very small. The next three pairs are also slender and elongated; the inner branches of the fouth pair, which are somewhat shorter tham the outer, are provided with a moderately long plumose seta near the middle of the inner margin of each of the three joints, two similar sete and a small spine spring from the apex of the last joint. The fifth pair are of moderate size; inner portion of primary joint narrow, subtriangular, and provided with a seta and two moderately stout spines on the inner margin and two setre at the apex; the secondary joint, which is rather narrow, subcylindrical for about three fourths of its length, then tapering obliquely to the pointed extremity, extends considerably beyond the end of the primary branch, and is furnished with two seter on the distal half of the inner margin, two on the onter margin, and one at the apex.

Furcal joints very short.
Hab. Dredged at Salcombe in 1875, and in Mill Bay, Plymouth, among algre, in August 1903.
'This may be distinguished from other described species by the stucture of the slender first pair of natatory legs and the peculiar form of the female filth pair.

## Stenhelia varians, sp. n.

In this species the female closely resembles Stenhelia neylecta, just described, but differs in the following more or less important particulars: - The first four joints of the eightjointed antennules are together nearly three times the entire length of the last four ; the second joint is the longest and is more than twice the length of the third, while the fourth is about one and a half times longer than the same joint; the next three joints are very small and subequal, but the end joint is about as long as the combined lengths of the two preceding ones, as indicated by the formula-

The outer rami of the second antenna are triarticulate, the middle joint being the smallest. The mouth-organs and natatory legs are similar to those of S. neglecte. The fifth
pair also resemble in some respects those of the species referred to, but differ somewhat in form and armature; the primary joints terminate in a narrower apex, and on the inner margin there are short and subequal setee and two slender terminal sete of unequal length; the space that separates this pair of setre from the nearest of the other three is distinctly wider than that which separates these three from one another; the secondary joints are subovate and nearly twice as long as broad; the outside edge is nearly straight, but the inner is broadly convex; a seta springs from near the middle of the outer margin and four from the angularly rounded extremity of the joint.

Furcal joints short.
IIab. Dredged outside the harbour at Fowey, Cornwall, May 12th, 1903 ; not common. No males were observed.

## Stenhelia longirostris, sp. n.

The form we describe under this name was dredged at Salcombe in 1875. It is not unlike S. reflex ', 'T. Scott, in its general appearance and in the structure of some of its appodages; it is, however, a smaller species, the specimen from which the description was prepared measured about $\cdot b 8 \mathrm{~mm}$. ( ${ }_{2}^{1}$ s of an inch) in length. Body subcylindrical, with the torehead produced into an elongated and rather slender rostrum. The first joint of the eight-jointed antemules in the female is slightly longer than the second and nearly twice as long as the third joint ; the fourth, which is aloo rather longer than the third, has the upper distal angle produced forward to near the end of the following joint to form the base of a long sensory filament; the fifth, sixth, and seventb joints are small and nearly equal in length, while the last is about twice the length of the preceding one. The formula shows approximately the proportional lengths of all the joints-

The three-jointed outer ramus of the second antennæ is of moderate length.

The first joint of the second maxillipeds bears two moderately long setre on the imner aspect of the distal end ; second joint narrow, subcylindrical, and furnished with a longitudinal row of spinules on its imner aspect, and a small seta near the middle and another near the end of the inner margin; terminal claw slender and moderately clongated. In the
first pair of natatory legs the proximal joint of the imner branches is about equal to the entire length of the outer, but the second joint is only about half the length of the thitd, while the second and third joints are together about equal to two thirds the length of the proximal joint; the joints of the outer branches are subequal. The next three pairs are similar to those in Stenhelia reflexa.

The filth pair has the imner portion of the primary joint produced into a narrow subtriangular plate, the bluntly rounded apex of which reaches to about the middle of the secondary joint; there are three sete on the inner margin, the upper two are short and subequal, the lower moderately elongated; there are also two slender and moderately long apical seter of unequal length. The secondary joint is moderately narrow and elongated, the breadth being scarcely half' the length; it is broadest near the proximal end and tapers gradually to the truncate and somewhat angular apex; a small seta springs from near the distal end of the inner margin, two of moderate length from the truncate apex, and three small ones from the lower half of the outer margin; that one of these three which is nearest the distal end is the smallest and is provided with a peculiarly thickened base.

No males of this species have been observed. The peculiar form and armature of the fifth pair of thoracic feet appar to be characteristic of the species.

The furcal joints in this species are short.

Genus Parastenifelia, I. C. Thompson \& A. Scott, 1903.

## Parastenkelia anglica, sp. n.

The genus Parastentelia was instituted by I. C. Thompson and Andrew Scott for two species which, though having a close resemblance to Stenkelia, differ in possessing ninejointed antennules, in the middle joint of the outer ramus of the antemm being nearly as long as the joint on either side, and in having the inner branches of the first natatory legs two-jointed, the first joint being considerably longer than the three-jointed outer branches. The form I have now to describe agrees so closely with the typical species that I have little hesitation in ascribing it to the same genus, even though the inner branches of the first pair of legs be apparently three-jointed. In this form the antennules are composed of nine joints; the first four are together equal to fully twice the entire length of the other five, the second is considerably
longer than the third or fouth, which are subequal; all the other joints are smaller, as shown by the formula-

Proportional lengths of the joints, 25.46. 34.34 .12 . $10.8 \cdot 6.16$.
Numbers of the joints

| 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |

The outer ramus of the second antenne is threc-jointed and moderately elongated, the middle joint being about as long as the end one.

The mandibles resemble those of Stenhelia; the basal joint of the mandible-palp becomes broader towards the distal end and is furnished with two uniarticulate branches, the distal one being more elongated than the other. The second maxillipeds resemble those of Stenhelia hispida, G. S. Brady.

The first thoracic legs have the inner branches very long and slender and apparently three-jointed; the first joint is about half the length of the second, but the end one is very shert; a plumose seta springs from the inner distal angle of the first joint, while the end joint bears two claw-like terminal spines of unequal length ; the outer branches reach to about the middle of the imner ones. The second, third, and fourth pairs are slender and moderately elongated ; in the outer branches of the fourth pair the first and second joints bear exteriorly a small spine near the distal end and a plumose seta on the imner margin, while the end joint is furnished with two terminal spines-one small and one long and slender -and a moderately long seta; the first two joints of the immer branches are each furnished with a seta on the inner margin, while two seta spring from the inner margin of the third joint, which also bears two setæ and a small spine at the apex. 'The fifth pair has a small primary joint, subtriangular in form and provided with five sete on the lower half of the inner margin and apex. The secondary joint is elongated, the upper portion is subcylindrical, the greatest breadth being equal to about a third of the entire length ; at about a third from the distal end the outer margin slopes gradually inwards till it meets the nearly straight inner margin; a single short seta springs from near the lower end of the inner margin and five from the distal third of the outer margin, the apical and middle setre being elongated, but the other three moderately short.

Furcal joints very short.
Hab. Dredged outside of Fowey Harbour, Cornwall, on May 9 th, 1903 ; rare. No males were observed.

Genus Ameira, Boeck, 1864.

Ameira simplex, sp. n.

Description of the female.-Body moderately slender; rostrum somewhat prominent; length $6 \pm \mathrm{mm}$. ( $4_{40}^{1}$ of an inch).

Antennules short, moderately stont, eight-jointed, first and second joints longer and somewhat more robust than the othere, third to the sixth short and subequal; the last two are also small, as shown by the formula-

Antenne small, outer ramus short and uniarticulate and provided with a few terminal setæ. Mandibles also small, mandible-palp simple and one-branched.

Imner branches of first natatory legs elongated and slender ; first and third joints nearly equal in length, second about hatf as long as the first ; the outer reach nearly to the end of the second joint of the inner branches. The other three pairs are also moderately slender, and the outer branches are rather longer than the imer ones.

Fifth pair small, inner portion of primary joint subcylindrical, with the apex obliquely truncated and bearing five setw, the second seta from the outside being much longer than the others. Stcondary joint subovate, length nearly twice the width at the proximal end, the outer and inner margins are only slightly rounded and taper gently towards the narrowly rounded apex; they are each furnished with five sete, four (three elongated and one-the second from the outside-smali) are carried on the rounded apex, and a small one on the preximal half of the outer margin.

The furcal joints are fully half as long as the last abdominal segment.

Ilab. Dredged in the estuary of the Exe, near Starcross, Juic 9 th, 1884 ; apparently rare. No males observed.

This species bears a close resemblance to Ameira exigux, T. Scott, but it differs to some extent in the proportional lengths of the joints of the antennules, in the armature of the mandille-palp, in the outer branches of the first thoracic feet being as long as first and second joints of the imer branches, as well as in the joints of the inner branches being different in their proportional lengths; the armature of the dith pair is also different in the two species.

## Genus Laforiontina, nov.

Somewhat like Laophonte in general appearance. Anterior antenne short and composed of about six joints. Outer ramus of posterior antema uniarticulate. First pair of natatory legs nearly as in Laophonte. Second and third pairs one-branched and more or less rudimentary. Fourth pair two-branched, outer branches three-, inner one-jointed. Fitth pair as in Laophonte. Only one species is known, which is described below.

## Laophontina dubia, sp. n.

Length of female about 5 mm ., male rather smaller. Boly somewhat slender. Antennules of the female short, six-jointed; first joint stout, longer than any of the others, and with a small tooth-like process near the middle of the exterine margin and another at the inner distal angle; second joint shorter than the first and armed exteriorly with a strong projecting tooth; third rather longer, but less robust than the second; fourth and fifth very small ; the last joint is longer than the fourth and fifth combined.

The male antemules are modified for grasping, but the first and second joints are similar to those of the female.

Posterior antenne moderately slender, outer ramus small and miarticulate.

First thoracic feet as in Laophonte; inner branches elongated, two-jointed; first joint long and slender, the other short and armed with a long stout terminal claw; imer branches very small and uniarticulate and furnished with a few small sete. Second pair rudimentary, one-branched, each composed of a single short but moderately stout joint, learing a few small setx. Third pair also rudimentary and one-branched, but the branch is two-jointed and bears two spiniform terminal sete. Fourth pair two-branched; outer branch short, stont, and three-jointed; the first and second joints bear moderately long and stout spinc-like sete on their outer margins; the end joint is very small and bears two apical sete, one long, the other shorter and spiniform ; inner branch small and miarticulate and furnished with elongated setre. The fourth pair in the male are smaller than in the female and the inner branches are nearly obsolete.
'I he fifth pair in the female moderately large and foliaceous; primary joints broadly triangular and provided with about four plumose seta, one at the apex and three on the inner nargin; sccondary joints ovate, the length being equal to
about twice the breadth; they are each provided with four plamose terminal sete.

In the male the fifth pair are very small and rudimentary.
Furcal joints slender and about equal in length to the last abdominal segment ; principal tail-setæ somewhat dilated at the base.

Hab. Dredged at St. Mary's, Scilly Islands, in May 1903.

Genus Dactylopusia, A. M. Norman, $1903 \%$.

Dactylopusia valida, sp. n.
This species resembles Dacty? popir tisboides (Claus) in its; general appearance and size. The eight-jointed antennules are short and stout ; the first and second joints are longer and the fifth and seventh shorter than the others; the other four, which are nearly of equal length, are each about a third shorter than the first or seconl, as shown by the formula-

The three-jointed outer ramus of the posterior antenne is moderately large and stout and provided with several seta. The mouth-organs resemble those of $D$. tisboides, but the second maxillipeds are moderately stout and their terminal claws elongated and slender.

The first pair of swimming-feet are moderately stout; the outer branches are rather more than half the length of the inner and armed exteriorly with strong spines; the first and second joints are very robust, their width being about equal to three fourths of the length; the end joint is very short and furnished with four spines and a seta; the spines are of unequal length, the two outer being very small, the other two strong and slightly clawed, the inner being the longer; the inner branches are also moderately stout, the first joint elongated, the second and third very short, and the third armed with one long and one short and stout terminal claw. The second, third, and fourth pairs resemble the same three pairs in D. tisboides.

In the fifth pair the primary joints are moderately elongated and reach to about the extremity of the secondary joints; they taper slightly to the rounded distal end, which

[^34]carries five setæ; the setæ are arranged in three groups-the two outer are close together, so also are the next two, but there is a moderately wide space between the two pairs of setæ and also between the imer pair and the last seta situated a small distance up on the inner edge; in the space between the outer and inner pairs there appears to be a small spine. The secondary joints are broadly ovate, the length being scarcely twice the width at the broadest part; the inner margin is nearly straight, but the outer is moderately convex; a small seta springs from the middle and an elongated one from near the distal end of the inner margin, while other five are arranged round the lower half of the outer margin and apex.

The furcal joints are very short.
Hab. Dredged near Beggar's Island, Plymouth, in 1889 ; apparently not very common.

This species is readily distinguished by the robust form and structure of the first pair of natatory legs, the stont eightjointed antennules, and the form and armature of the fifth feet.

## Dactylopusia ornata, sp. n.

Description of the female. - Body moderately robust; length -62 mm . ( $\frac{1}{40}$ of an inch).

Antemnules short, moderately stout, and composed of six subequal joints. Outer ramus of posterior antenne apparently only two-jointed. Mouth-organs as in D. rostratus, T. Scott.

The first thoracic legs are short and stout; the threc-jointed outer branches are rather shorter than the first joint of the inner ones; the first two joints have the outer margin fringed with short setx, and a setiferous spine springs from their outer distal angles; the second joint bears also a plumose seta on its inner margin; the end joint is small and bears several spiniform apical seta. The imner branches appear to be only two-jointed; the first is stout and elongated, and bears a long plumose seta on its inner margin ; the end joint is short and probably composed of two coalescent joints, it is furnished with a stout and slightly curved claw-like terminal spine. The next three pairs resemble those in D. rostrata (I'. Scott).

The fitth pair are broadly lamelliform; the primary joint bears inteniorly five seta of unequal lengths on the broadly rounded distal edge; the secondary juint is subquadrangular and carries five stout sete, one being near the distal end of
the outer margin, three on the truncated apex, and one on the inner margin.

The furcal joints are very short.
The male does not differ greatly from the female except in the following particulars:-the antennules are modified for grasping, the outer branches of the second thoracic feet are armed with stronger spines than the same pair in the female, and the inner branches are only two-jointed, and the terminal spine is stout and claw-like.

The fifth pair are rather smaller than those of the female and the inner and broadly rounded portion of the basal joint bears only two apical spines.

Hab. Dredged at various places on the coast of Devon; moderately frequent. Also at Fowey, Cornwall, and New Grimsby Harbour, Scilly Islands.

Recently collected specimens were easily recognized by their peculiar colour, which was for the most part of a uniform yellow or, in some examples, yellowish grey; but what rendered the specimens so conspicuous was a band of a fine purple colour which adomed the posterior portion of the cephalic segment ; this band, which covers about a third of the segment, does not extend right across, but terminates on each side a short distance from the lateral margins; moreover, the posterior edge of the band is even and coincides with the edge of the cephalic segment, but the anterior edge is deeply crenulated. Immersion in methylated spinit speedily destroys the purple colour, but the colour remains intact for a considerable time if specimens be preserved in formalin.

## Dactylopusia purpurocincta, sp. n.

In this species the body is depressed, but moderately stout, and in general appearance resembles $D$. flava, Claus; length about 5 mm .

Seen from above the cephalothoracic segment is broadly and evenly rounded in front and about as long as the remaining segments of the thorax ; the three segments immediately posterior to that of the ceplalothorax are of a dark purplish-brown colour, but the ground-colour of the body is light yellowish.

The antennules are short and stout and appear to be composed of seven joints ; the first and second, which are robust, are longer than the others. The formula shows approximately the proportional lengths of the various joints-

$$
\begin{aligned}
& \text { Proportional lengths of the joints. . } 14 \cdot 13 \cdot 8 \cdot 8 \cdot 5 \cdot 3 \cdot 7 \\
& \text { Numbers of the joints............ } 1: 2
\end{aligned}
$$

Antenne stout, outer rami slender, of molerate length, and apparently only two-jointed.

The first pair of swimming-feet short and robust: outer branches considerably shorter than the inner and furnished with long, spiniform, coarsely plumose setre on the outer margin; inner branches apparently only two-jointed, the first joint longer than the entire outer branches and strongly dilated interiorly, as in the male of D. Alava, second and third joints coalescent and bearing a short stout terminal claw and a moderately long spiniform seta. The next three pairs are somewhat similar to those of $D$. tisboides.

The fifth feet are moderately large; primary joint a broadly quadrangular lamelliform plate bearing five strong, plumose, spiniform setre on the distal margin, which is broadly truncate; a comparatively wide space separates the outermost seta from the one next to it. Secondary joint subcylindrical, but becoming narrower from about the middle of the joint to the end; imer margin nearly straight, with a short seta on the lower half; two stout spinc-like sete spring from the lower half of the outer margin and two from the apex.

Furcal joints very short.
Male unknown.
Hab. Dredged at Salcombe, June 30th, 1875.
This form closely resembles $D$. laticaudata and $D$. cemula, described by I. C. Thompson and A. Scott in their Report on the Copepoda collected by Professor Herdman at Ceylon in 1902. The two species, with that just described, differ in some respects from the typical Dactylupusia, and, as surgested by the authors referred to, " may some time require a separate genus." The coloured band in this species appeared to be quite unaffected by the long immersion in methylated spirit, forming a marked contrast to the evanescent colour of 1). ornata.

## Genus Peltidium, Philippi, 1839.

## Peltidium conspicuum, sp.n.

A single specimen of an apparently undescribed Peltidium was obtained in New Grimsby Harbour, Scilly Islands, May 23rd, 1903. It was of a uniform dark purple or ruby colour, and therefore conspicuous in the sample in which it occurred.
$I^{\prime}$. conspicuum has a general resemblance to $P$. purpureum, Philippi, but is rather larger, and the carapace wants the pellucid areas so charactoristic of that species, being, on the
contrary, of a dense uniform purple or ruby colour. It measures about 1.3 mm . ( $\frac{1}{9}$ of an inch) in length. The rostrum truncated, not much produced, the truncated end being obscurely tridentate.

Antemnules short, stout, and six-jointed ; first three joints subequal and about twice the entire length of the last three, the penultimate joint being very small; antenne and mouthorgans as in $P$. purpureum.

The first pair of swimming-feet resemble those of the same species, but the first and second joints of the outer branches are of nearly equal length; they each bear a short seta near the middle of the outer margin and a similar seta near the distal end of the inner margin ; the end joint is very slort and furnished with three claws (two stout and of moderate length and one short) and a small seta. The inner branches are stout and composed of two joints; a seta springs from the distal end of the inner margins of the first and second joints, but the second joint is also furnished with two apical setæ. The second, third, and fourth pairs are apparently similar to those of $P$. purpureum. In the fifth pair the primary joint appears to be short and bears one seta on the outside and two on the inside distal angles; the second joint is also short and provided with six stout plumose seter on the lower half of the outer margin and apex.

The first segment of the abdomen forms a trilobed plate which entirely overlaps the remaining abdominal segments and furcal joints, and in this respect differs very markedly from other described species; in these the last abdomiual segment and furcal joints are exposed.

## Genus Mesocheres, nov.

Body somewhat similar in general appearance to Scottocheres, Giesb., the cephalothorax seen from above being ovate in outline, while the abdomen is narrow and elongated. The antennules are composed of twenty-one joints and are similar in structure to those of Asterocheres. The antenne also resemble those in the same genus. The mandibles and maxillæ were damaged and could not be satisfactorily made out. The first maxillipeds are small but moderately stout, their terminal claws clongated and strongly hooked and with an elongated spine attached near the base of the claw. Second maxillipeds long and slender, and similar in structure to the same appendages in Asterocheres. First four pairs of swimming-fect somewhat similar to those of the same genus. Fifth pair very small and apparently two-jointed.

Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.

This genus partakes of the characters of the two genera Asterocheres and Scottocheres, but differs from both as described above.

## Mesocheres anglicus, sp. n .

Cephalothorax of the female ovate, moderately robust, widest in the middle, the width being equal to fully half the lengeth; first segment about one and a half times longer than the other segments combined: abdomen narrow and elongated, as in Scottocheres longifurca, Giesb., and composed of three segments, the first rather longer than the second and thiyd together; it is widest at the proximal end and produced on each side into a hook-like process, as in the Scottocheres referred to ; the anal segment is the smallest of the three, being only a little more than half the length of the preceding one. The furcal joints are long and slender and about four times as long as the last segment of the abdomen; the outer edge of each joint is fringed with minute bristles, and the principal apical sete are only moderately elongated. Length about 65 mm . ( 13 of an inch).

Antemules composed of twenty-one joints and somewhat similar in structure to those of Asterocheres Boecki; a moderately stout sensory filament springs from the end of the eighteenth joint. Antennæ three-jointed, the first joint longer than the next two together, the third small and furnished with one long and two short apical setæ; outer ramus small, uniarticulate, with one or two slender apical setr.

First maxillipeds short, armed with elongated, stout, strongly curved terminal claws; a moderately long spiniform seta springs from near the base of the claw. Second maxillipeds long, slender, and similar to the same appendages in Asterocheres Boecki.

First four pairs of swimming-feet somewhat similar to those of the same species, but the armature differs to some extent, and especially that of the fourth pair ; in this pair the spines on the onter margin and apex of the outer branches are large and broadly dagger-shaped, and they are all, with the exception of the immer terminal spine, finely serrated on both edges, but the inner terminal spine is only serrated on the outer edge; the first and second joints are also provided with a plumose seta on the inner margin, while the last joint bears four plumose setæ on the inner margin in addition to the four large spines on the outer margin and apex. The first joint of the inner branches bears one seta and the second and third joints two setie on the inuer margin ; a similar seta
springs from a notch near the middle of the outer margin of the third joint, which is also armed with a large dargershaped terminal spine. The fifth pair are very small; tho primary joint is nearly twice as broad as it is long and bears a single spiniform seta on the exterior distal angle; the secondary joint is indistinctly trilobed and carries two or three setæ.

IIab. Dredged in Plymouth Sound on August 12th, 1903.

## Genus Herrmanvellá, Canu, 1891.

## Herrmannella parva, sp.n.

Description of the female. -Similar in general appearance to H. rostrata, Canu, but smaller; length of the specimen described 68 mm . ( ${ }_{3}^{\frac{1}{7}}$ of an inch).

Antennules short and composed of seven joints, the proportional lengths of which are given in the formula-

Proportional lengths of the joints.. $14.34 .8 \cdot 19.19 .14 .8$.
Numbers of the joints. . . ......... $1 \begin{aligned} & 1 \\ & 2\end{aligned} 3 \quad 4 \quad 5 \quad 6 \quad 7$.
Antennæ stout, four-jointed, but the penultimate joint is very small ; terminal setæ curved, claw-like, and exhibiting a pseudo-articulation near the middle, as in some species of the Lichomolgidæ.

Mandibles in the form of broad falciform plates, which taper gradually to the acuminate apex. Maxillæ subcylindrical, simple in structure, and bearing each a small marginal and apical seta. First maxillipeds short, stout, and armed with a slender, curved, terminal appendage, bearing a unilateral row of small spinules, while a moderately long spiniform seta springs from the inner margin and near the base of the curved terminal appendage. The second maxillipeds are moderately stout, two-jointed, and provided with a stout terminal claw, as in Lichomolgus liber, Brady and Robertson.

The thoracic feet are somewhat similar to those of Herrmannella rostrata, Canu, but are scarcely so stout; both branches of the fourth pair are three-jointed; the first and second joints of the outer branches have each a small daggershaped spine at the distal end of the exterior margin, while the third joint has a similar spine in the middle of the outer margin and two apical spines, the inner one being about as long as the joint from which it springs; moreover, the second joint bears one long plumose seta and the third five similar setr on the inner margin; the first and second joints of the inner branches have each a single seta near the distal end of
the inner margin, while the third joint bears only two terminal spines, the imner one stout and about twice as long as the other. Fitth pair very small ; each foot consists of a single joint which bears two small terminal seta.

The abdomen is moderately slender and composed of four segments; the genital segment is somewhat dilated and about equal in length to next three segments taken together; the second and third segments are small, while the fourth is rather longer than the preceding one.

The furcal joints are about twice as long as the last abdominal segment ; each joint is furnished with several terminal seta, and a single small bristle springs from near the middle of the outer edge.

Ilab. Taken in Plymouth Sound, among Hydrozoa \&c., near low-water, in August 1 03; rave.

This small species resembles a diminutive $P$ seudanthessius gracilis, but the structure of the fourth pair of thoracic legs shows that its relationship is with Canu's genus Herrmannella. It differs, however, from any Ilermannella hitherto described by the form of the mandibles, the proportional lengths of the abdominal and furcal joints, and one or two other points mentioned in the description.

## XXXIV.-Descriptions of Two new Cyprinid Fishes from Libet. By C. 'Tate Regan, B.A.

## Gymnocypris Waddellii.

Pharyngeal teeth 4:3-3:4, cylindrical, obtusely pointed, slightly incurved. Depth of body about 5 in the length, length of head about 4 . Breadth of head about $1 \frac{3}{4}$ in its length, diameter of eye $6-8$, length of snout $3 \frac{1}{3}-3 \frac{2}{3}$, interorbital width $3-3 \frac{1}{3}$. Sncut obtuse; mouth terminal, oblique ; anterior edge of upper jaw not below the level of the lower margin of eye; maxillary nearly reaching the vertical from the anterior margin of eye. $10-13$ gill-rakers on the lower part of the anterior arch, 2 or 3 on the upper part. Dorsal III 8 , its origin a little nearer to tip of snout than to base of caudal; third simple ray slender and articulated above, slightly thickened and finely serrated in its basal half (in the two smaller examples), or not serrated (in the two larger ones). Anal III 5, extending to the base of caudal when laid back. Origin of ventral below about the middle of dorsal.

Caudal forked. Caudal peduncle about $2 \frac{1}{2}$ as long a; deep. Greyish above, silvery below. Head, body, and fi:ns (the ventrals sometimes excepted) coverel with dark spots of small or moderate size.

Four specimens, $300-400 \mathrm{~mm}$. in total length, from th, Yamdok Lake, a large lake without outlet at an altitude of 14,800 feet. They were obtained by Lieut.-Col. L. A. Waddell, C.B., who preserved them in salt and has presented them to the British Museum.

## Nemachilus lhasce.

Depth of body $7 \frac{1}{3}$ in the length, length of head $4 \frac{3}{4}$. Surut a little longer than postorbital part of head, twice as long as eye, the diameter of which is $4 \frac{2}{3}$ in the length of head and equal to the interorbital width. Breadth of head $1 \frac{2}{3}$ in its length and very slightly greater than its depth. Cleft of mouth extending to below the nostrils; lips moderately thick, plicated, the lower interrupted medianly; barbels six; outer rostral barbel nearly reaching the middle of the masillary barbel, which is $1 \frac{1}{2}$ the diameter of eye. Scales entirely wanting. Dorsal II 9, its origin nearly equidistant from tip of snout and base of caudal; free edge of the tin concave. Anal II 5. Pectoral extending $\frac{5}{7}$ of the distance from its base to the base of ventrals. Ventrals 9 -rayed, extending to the origin of anal. Caudal emarginate. Caudal peduncle slender, $6 \frac{1}{2}$ as long as deep and $1 \frac{1}{5}$ the length of head. Olivaceous, with traces of darker cross-bars on the back; dorsal and caudal fins with small dark spots.

A single specimen, 84 mm . in total length, from Lhasa, collected by Capt. H. J. Walton.

Allied to N. stemurus, Herz.
When writing my descriptions of the Cyprinid fishes collected by Capt. Walton (suprà, p. 185) I overlooked this specimen.
XXXV.-On new Species of Histeridæ and Notices of others. By G. Lewis, F.L.S.
This paper is written to found a new genus and to describe three new species, the names of which are given in the 'Catalorue of Histeride' which will shortly be published. It is the twenty-fourth of the series in this Magazine; the previous paper is in vol. xiv. p. 137 (1904).

## Cylistosoma, gen. nov.

Body elongate, cylindrical; head retractile, with a frontal stria; thorax, antemal fossettes widely open below; elytra striate, striæ sometimes complete; prosternum compressed, striate in the typical species, rounded off at the base and received into the mesosternum; mesostornum emarginate or widely sinuous anteriorly; anterior tibia dentate on the outer edge.

I consider Platysoma Richteri, Sch., the type of Cylistosoma, and closely similar to it are other species from Madagascar, viz. Plutysoma (Teretrius) Furmairei, 'lhéry, obliquum, Lew., pulvinatum, Sch., quadricolle, Lew., and in all of these the prosternal keel is distinctly striate. In the Catalogue I lave associated all the cylindrical Platysome temporarily with the above, because the genus Platysoma as it has hitherto stood cannot be conveniently studied without division.

## Hololepta trulla, sp. n.

Elongata, parallela, depressa, nigra, nitida; fronte haud striata; elstris, striis 2 dorsalibus brevissimis, $1^{\text {a }}$ appendiculata; propygidio sulco arcuatim integro, utrinque foveolato; pygidio impunctato.
L. $7 \frac{1}{4}$ mill. (absque mandibulis).

This species is extremely similar to II. paropsis, Lew., but it is more parallel laterally; the male has no thoracic fossex, the arched sulcus on the pygidium is somewhat angulate in the middle (not formed as a Moorish arch, as in II. paropsis), and posteriorly on the inner edges of the sulci are shallow but well-marked foveæ, one on each side. There is no trace of a carina on the mentum in the male.

Hab. Lake Tanganyika, Central Africa.

## Lioderma acutipectum, sp. n .

Oblongum, subconvexum, nigrum, nitidum; fronto haud striata; elytris, striis, 1 brevi, 2 integra, 3 brerissima; propygidio circum parce punctato; pygidio dense punctato; prosterno ante coxas angustato.
L. 12 mill. (absque mandibulis).

Oblong, somewhat convex, black and shining; the head is nearly flat on its vertex and is without strix, and the mentum of the male is not carinate; the thorax, the marginal strix terminate near the eyes and the male has no fossettes, behind the anterior angles a few vague punctures are visible;
the elytra, subhumeral furrow is shortened at either end, tho first dorsal stria is basal and is one thitd of the elytral lengeth, the second is well marked and complete and evenly bent thronghout its entire length, the third very short and basal; the propygidium is scantily punctate laterally; the pegidium is somewhat convex and densely punctate ; the prosternum is triangulate at its base, but before the coxa the keel is narrow like that of Oxysternus, hence its trivial name; the anterior tibice are 4 -dentate.

The prosternal keel is similar to that of Lioderma dorcoidos, Lew. Hololepta strigilat, Sch., from East Atrica, also has a narrow prosternal keel, and should therefore, I think, be placed in Lioderma.

Hab. Kamerun, West Africa (Dr. Sjöstedt). One male example in the Stockholm Museum.

## Hister laqueatus, sp. n.

Broviter ovalis, parum convexus, niger, nitidus; fronte, stria integra in medio retrorsum acuminata; pronoto, stria laterali ralida, basi abbreriata, ad angulos punctato ; elstris, striis 1-3 validis, integris, 4 basi evanescenti, 5 et suturali basi conjunctis; propygidio pygidioque levibus; tibiis anticis extus 4 -dentatis.
L. $4 \frac{3}{4}-\frac{1}{4} \frac{1}{4}$ mill.

Shortly oval, somewhat convex, black and shining; the head, surface punctulate, feebly impressed anteriorly, stria complete, strong at the sides, and acuminately turned backwards anteriorly; the thorax, lateral stria strongly impressed, well shortened before the base, and continued behind the head, within the stria the anterior angles have a cluster of punctures, the basal edge is also pointed ; the elytra, strix, imner humeral strong, apical, and dimidiate, 1-3 dorsal also strong and complete, interstice of $2-3$ is wide at the base, 4 is evanescent or vaguely impressed at the base, 5 and sutural are looped together at the base, but the fifth is lightly impressed on the dorsum; the propygidium and the pygidium are nearly smooth, the punctuation being extremely fine; the prosternum, the anterior lobe is finely marginate, keel without strix and narrowed between the coxr ; the mesosternum is widely arched anteriorly and marginate; the anterior tibire are 4 -dentate on the outer edge.

On account of its general sculpture this species may be placed near II. conformis, Er., and II. rubricatus, Lew. The inner subhumeral strie are similar in all.

Llab. Kamerun (1)r. Sjöstedt). In the Stockholm Museum and my own collection.
XXXVI.—Rhynchotal Notes.-XXX. By W. L. Distant.

Subfam. Cicadivac (continued from p. 70).

## Division Lahugadaria.

This division is primarily divergent from Dundubiaria by the non-dentate lateral margins of the pronotum; the tympana are completely covered, the tympanal flaps broader than long; the opercula short, somewhat globose, wider than abdominal margin, and distinctly visible from above.

## Lahugada, gen. nov.

Head (including eyes) considerably narrower than base of mesonotum, its length about equal to space between eyes, its lateral margins discontinuous, the lateral margins of front being almost at right angles to those of vertex; pronotum almost as long as mesonotum, narrowed anteriorly, the posterior angles prominent and rounded; abdomen considerably longer than space between apex of front and base of cruciform elevation; tympana completely covered, tympanal coverings broader than long; opercula short, somewhat globose, wider than abdominal margin, and distinctly visible from above; rostrum about reaching the posterior coxa; tegmina and wings hyaline, the first with eight apical areas and the basal cell longer than broad.

Type, L. Dohertyi, Dist. (Pomponia).

## Subfam. $G_{\text {EAninew }}$

I propose this subfamily for the reception of a considerable number of genera in which the tympanal coverings are present but imperfect and the tympanal orifices are more or less exposed.

Three subfamilies may be thus differentiated :-
A. Tympanal coverings present.
a. Tympanal coverings entirely concealing tympanal orifices

Cicadine.
au. Tympanal coverings imperfect, more or less exposing tympanal orifices

Geanine.
B. Tympanal coverings absent ............................ Tibicinince.

## Division Cicadatraria.

In this division the tympanal coverings are rounded antefiorly, not angulate-either completely covering the orifices
anteriorly and exposing them interiorly or the reverse, or smaller, exposing them both anteriorly and interiorly; the lateral margins of the pronotum are not convexly ampliate nor medially angulate; the tegmina and wings are hyaline, sometimes maculate.

The genera composing this division are confined to the Palæarctic, Oriental, and Malayan regions and represented in Japan.

## Synopsis of Genera.

## 1. Abdomen not tuberculate beneath.

A. Tympanal coverings narrower, but scarcely shorter than tympanal cavities.
a. Lateral margins of pronotum moderately ampliate.
b. Head shorter than pronotum.
c. Abdomen longer than space between apex of head and base of cruciform elevation ......
ca. Lateral margins of pronotum straight, not ampliate.
bb. Head as long as pronotum.
cc. Abdomen short, about as long as space be-
tween apex of head and base of cruciform
cc. Abdomen short, about as long as space be-
tween apex of head and base of cruciform eleration

Tettigia.

Emathia.
B. Tympanal coverings both narrower and shorter than tympanal carities.
d. Opercula in $0^{*}$ short and transverse, not or scarcely extending beyond base of abdomen.
$e$. Head deflected anteriorly, front not prominent.
$f$. Pronotum distinctly shorter than mesonotum.
g. Length of head about equal to breadth between eyes; abdomen in $\delta$ longer than space between apex of head and base of cruciform elevation.
$h$. Greatest width of tegmina only one third of length, broader than wing's

Terpnosia.
$h h$. Greatest width of tegmina considerably nore than one third of length, but scarcely broader than wings

Sena.
gg. Length of head less than width between eyes; abdomen in $\delta^{*}$ about as long as space between apex of head and base of cruciform elevation

Cicadatra.
$d d$. Opercula in ot short but well developed, at least reachitis the apex of the second abdominal segment

Khimbyu.
ddd. Opercula in $\delta^{*}$ extending beyond the middle of abdomen.
ee. Head not deflected anteriorly, the front very prominent.
ff. Pronotum as long as mesonotum .......... Lethame.
C. Tympanal coverings shorter, but not narrower than
tympanal cavitios.
eee. Head with the front prominent, its lateral margins at right angles with anterior margins of vertex.
h. Lateral margins of pronotum ampliate, narrowedanteriorly.i. Abdomen beneath strongly channelled nearlateral marginsKamalata.$h h$. Lateral margins of pronotum convex ante-riorly, medially concavely sinuate.ii. Abdomen beneath obliquely recurved nearlateral marginsBasa.
2. Ablomen in $\delta^{7}$ tuberculate beneath on the second and third abdominal segments Calcagninus.

## Genus 'Iettigia.

Tettigia, Kolenat. Mel. Ent. vii. p. 6 (1857). Type, T. orni, Limn. (Cicada).

## Genus Emathia.

Emathia, Sti̊l, Hem. Afr. iv. p. 8 (1866).
Type, E. agrota, Stål.

## Genus Terpnosia.

Termosia, Dist. Ann. \& Mag. Nat. Hist. (6) ix. p. $32 \tilde{0}$ (1892).
Type, T. psecas, Walk. (Dundubia).
Terpnosia confusa, sp. n.
Body above castaneous brown, finely greyishly pilose; pronotum with the centre of the posterior margin (excluding a medial spot), the apices of the lateral margins, and two central curved fasciæ pale greenish; mesonotum with the anterior lateral margin pale greenish, the margins of two obscure anterior obconical spots and the anterior angles of the cruciform elevation ochraceous; posterior margins of the aldominal segments narrowly fuscous; body beneath considerably paler in hue than above; opercula broad, transverse, convexly rounded posteriorly, not quite reaching basal segment of abdomen ; rostrum just reaching basal abdominal segment. Tegmina and wings hyaline, the veins brown or brownish ochraceous; tegmina with a slight greenish suffusion, a curved series of about four small fuscous spots extending from base of second ulnar area to inner margin, the bases of the two upper apical areas a little infuscated, and a narrow congate fuscous spot at apices of the longitudinal veins to apical arcas. Tympanal covering very small, the greater part of the tympana being exposed.

Long., excl. tegm., ठ 35 mm . ; exp. tegm. 87 mm .
Hab. "India " (Brit. Mus.) ; Sikhim (Coll. Dist.).
This is the species figured in my Mon. Orient. Cicad. (tab. vii. fig. 21) as T. psecas, Walk.

## Genus Sena.

Head about as long as space between eyes, lateral margins of front somewhat at right angles to lateral margins of vertex, eyes scarcely projecting beyond the anterior angles of the pronotum ; pronotum shorter than the mesonotum, its lateral margins more or less oblique, the posterior angles being obliquely dilated; abdomen longer than the space between apex of head and base of cruciform elevation ; tympana largely exposed, the flaps being a little shorter and very much narrower than the tympanal orifices; rostrum just passing the intermediate coxa; opercula in male small, transverse, not extending beyond base of abdomen; anal appendages large.

Type, S. quarula, Pall. (Cicada).

## Genus Cicadatra.

Cicadatra, Amyot, Ann. Soc. Ent. Fr. v. p. 153 or 349 (1847).
Type, C. atra, Oliv. (Cicada).
Khimbya, gen. nov.
Head deflected before eyes, the front scarcely visible above, its length much shorter than space between eyes, margins of front and vertex subobliquely continuous; pronotum distinctly shorter than mesonotum, its lateral margins sinuate, but not dentate; abdomen much longer than space between apex of head and base of cruciform elevation; tympana imperfectly covered, flaps shorter and narrower than tympanal cavity; rostrum not quite reaching posterior coxe ; opercula in male inwardly obliquely divergent, extending to a little more than a third of the abdomen; anterior femora with at least two spines on their under surface; tegmina broad, their greatest breadth considerably more than a third of their length, apical areas eight, basal cell much longer than broad.
'Type, K. evanescens, Walk. (Dundubia).
Lethama, gen. nov.
Head horizontal, as long as space between eyes, not anteriorly deflected, front very preminent, margins of front and
vertex obliquely subcontinuous; pronotum as long as mesonotum, its lateral margin oblique, sinuate, obscurely dentate ; abdomen considerably longer than space between apex of head and base of cruciform clevation; tympana imperfectly covered, the flaps shorter and narrower than the tympanal cavities; rostrum about reaching the posterior coxa; anterior femora armed beneath with two or three strong spines; opercula extending to more than half the length of the abdomen, situate wide apart and on the lateral abdominal areas ; tegmina broad, their greatest breadth more than one third of their length, apical areas eight, basal cell much longer than broad.

Type, J. locusta, Walk. (Cephaloxys).

## Genus Kamalata.

Kamalata, Dist. Amm. \& Mag. Nat. Hist. (6) iii. p. 52 (1839) ; Mon. Orient. Cicad. p. 124 (1892).
Head moderately deflected in front of eyes, its length about equal to space between eyes, its lateral margins discontimnous, the lateral margins of vertex being more or less at right angles to those of front, its width between eyes being distinctly narrower than base of mesonotum ; face globose; pronotum a little shorter than mesonotum, its lateral margins somewhat angulately sinuate, broad and laminate on posterior half ; abdomen broad, robust, and moderately inflated, above somewhat laterally oblique on each side, beneath strongly channelled near each lateral margin ; tympanal coverings about as broad but shorter than the tympanal cavities, their length variable, either very short as in K. pentherina or about halt the length of cavities as in $K$. javanensis ; opercula in male short, transverse, not extending beyond base of abdomen; rostrum considerably passing the posterior coxx; anterior femora strongly spined beneath; tegmina and wings hyaline, the first maculate, variable in length, about as long as body, as in $K$. pantherina, or longer than body, as in K. javanensis, basal cell longer than broad; apical areas eight.

I'ype, K. pantherina, Dist.

## Kamalata javanensis, sp. n.

$\delta$. Body castancous, finely greyishly pilose; head with transverse striations and a basal spot to front, and two spots both above and beneath the area of the ocelli, pale
ochraceous; pronotum with the posterior margin piceous, the lateral margins brownish ochaceons, a faint central longitudinal ochraceous line, and an ill-defined subverted angular spot at anterior margin, and the incisures, piceous; mesonotum with two anterior obconical spots only denoted by their piceous margins; cruciform elevation flavescent ; posterior margins of the abdominal segments narrowly piceous, and the extreme lateral margins of the same colour ; heal beneath, sternum, legs, and opercula ochraceons, space between face and eyes and apex of rostrum piceous; tramserse striations to face more or less castancous; tegmina and wings liyaline, the veins ochraceous or brownish ochraceous; tegmina with a curved series of about four fuscous spots between radial area (near apex) and inner margin, the veins scparating the ulnar and apical areas broadly infuscated, and a fuscous spot at the apices of the longitudinal veins to apical areas.

Long., excl. tegm., ठ 32 mm . ; exp. tegm. 85 mm .
Ilub. Java (Paris Muso).
Differs from $K$. pantherina by the longer tympanal coverings, which are about half the length of the cavities, and by the longer tegmina, which are considerably longer than the body; spots and markings also different.

## Basa, gen. nov.

Head with front prominent and produced, its lateral margins at right angles with anterior margins of vertex, its breadth between eyes much narrower than base of mesonotum, its length about equal to that of pronotum; pronotum a little shorter than mesonotum, its lateral margins convex anteriorly and concavely sinuate before posterior angles, which are ampliated; abdomen much longer than space between apex of head and base of cruciform elevation, its lateral areas obliquely depressed above; beneath with the disk somewhat flat and the marginal areas obliquely directed upward; tympanal flaps shorter, but not narrower than tympanal cavities; opercula transverse and just passing base of abdomen ; anterior femora strongly spined beneath near apex; anterior tibire longer than femora, anterior tarsi more than half the length of tibie; tegmina and wings long and narrow, greatest width of the first only equal to a third of length, its basal cell much longer than broad, fourth ulnar area much compressed at base of third, apical areas eight.
'Type, B. singultris, Walk. (Dundubia).

## Genus Calcagnixus.

Calcagninus, Dist. Mon. Orient. Ciead. pp. 31 \& 136 (1889).
Type, C. picturatus, Dist. (Leptopsaltria).

## Division Fidicinaria.

This division is represented by a series of Neotropical genera, in all of which the tympanal orilices are more or less exposed; the tympanal flaps are always well developed and are usually somewhat angulate at their apices; the tegmina and wings are hyaline, sometimes maculate, but never opaque, they always possess eight apical areas; the lateral margins of the pronotum have sometimes their posterior angles lobately produced, but they are never convexly ampliate nor medially angulate.

## Synopsis of Genera.

1. Metasternum with a moderately elevated transverse central plate, which is not anteriorly angularly produced.
A. Head (including eyes) about equal in width to base of mesouotum; eyes scarcely projecting beyond anterior angles of pronotum.
a. Vertex of head at area of ocelli distinctly longer than front.
b. Posterior angles of pronotum a little prominent, but not lobately produced.
c. Tegmina with transverse vein at base of second apical area more or less vertical

## Proarna.

$a \boldsymbol{a}$. Vertex of head at area of ocelli often only very slightly longer than front.
cc. Tegmina with transverse vein at base of second apical area strongly oblique

Tympanoterpes.
B. Head (including eyes) considerably broader than base of mesonotum; eyes projecting beyond anterior angles of pronotum.
bb. Posterior angles of pronotum more or less lobately produced.
d. Tympanal coverings large and only moderately internally deficient.
$e$. Tegmina with transverse rein at base of second apical area more or less vertical.
$f$. Vertex of head at area of ocelli about as long as front

Ollanta.
ff. Vertex of head at area of ocelli much longer than front.

## Pacarina.

dd. Tympanal coverings only developed on lateral areas.
ec. Tegmina with transverse rein at base of second apical area strongly oblique ...

Ariasa.
2. Metasternum transversely elevated and anteriorly angularly or subangularly produced.
C. Head (including eyes) about as wide as base of
mesonotum; eres not porrect
Fidicina.
D. Head (including eyes) considerably broader than base of mesonotum; eyes porrect, more or less stylate.
g. Pronotum about as long as mesonotum ; tympanal coverings in of with their inner margius strongly concave

Hemisciera.
gg. Pronotum shorter than mesonotum; tympanal coverings in ot not concave interiorly

Majeorona.

## Genus Proarna.

Proarna, Stal, Stett. ent. Zeit. xxv. p. 61 (1864); Hem. Afr. iv. p. 7 (1866).

Type, P. hilaris, Germ. (Cicada).
Some confusion may arise in separating this genus from Tympanoterpes, Stål (Ann. Soc. Ent. Fr. (4) i. p. 614, 1861), in which the founder had previously placed several of the species which he afterwards included in Proarna, and which again subsequently, in "Conspectus generum" (Hem. Afr. iv. p. 7,1866 ), he separates primarily by the moderately erect or curved and non-oblique transverse vein at the base of the second apical vein to the tegmina.

## Proarna Ieidemanni, sp. n.

Body above and beneath with legs pale virescent; vertex of head crossed by a prominent black transverse fascia between the eyes; incisures to pronotum, two small anterior obconical spots to mesonotum, and the tarsi pale fulvous; tegmina and wings hyaline, extreme bases of both pale fulvous, the venation of both and costal membrane and area to tegmina pale virescent. Head (including eyes) about equal in width to base of mesonotum, eyes slightly projecting beyond the anterior angles of pronotum; vertes of head at area of ocelli longer than front; posterior angles of pronotum obtusely angulately prominent, but not lobately produced; rostrum just passing the intermediate coxæ, its apex piceous ; opercula not extending beyond base of abdomen; tegmina with the transverse vein at base of second apical area almost vertical, not oblique.

Long., excl. tegm., of 16-18 mm. ; exp. term. 43-47 mm.
Mab. Argentina (Wagner, Brit. Mus.); Paraguay, Sapucay (Heidemann Coll.).

I have named this species after Mr. O. Heidemann, of

Washington, who has sent me a specimen of this species and has also assisted my revision by procuring me examples of many North-American species for comparison.

Proarna bufo, sp. n.
Body pale castaneous, finely and obscurely griseously pilose; area of the ocelli and mesonotum more or less piceous, the last with the lateral margins and the margins of two central anterior obconical spots pale castaneous; a spot at apex of front, lateral margins of vertex of head, lateral margins of pronotum, and cruciform elevation ochraceous; tegmina and wings pale hyaline, the first with about basal half of venation and the costal membrane and area ochraceous, remaining venation brownish ochraceous, a strongly broken curved linear fascia consisting of a little more than the basal vein of the second ulnar area, a spot on the posterior vein of third ulnar area, and a little more than the transverse vein at the base of lower ulnar area infuscate; small spots at transverse veins to apical areas, and a series of rather larger outer marginal spots, fuscous. Abdomen in male short and broad, about as long as space between apex of head and base of cruciform elevation; head (including eyes) slightly narrower than base of mesonotum, eyes not projecting beyond anterior angles of pronotum ; vertex of head at area of ocelli longer than front; posterior angles of pronotum only moderately subangulately produced, its lateral angles a little convexly rounded; rostrum reaching the posterior coxæ; tegmina with the transverse vein at base of second apical area somewhat vertical, not oblique.

Long., excl. tegm., of 20 , if 28 mm . ; exp. tegm., 才i 우 $55-57 \mathrm{~mm}$.

IIab. Argentina (S. W. Thomas, Brit. Mus.) ; Bolivia (Steinbach, Brit. Mus.).

Allied to P. Bergi, Dist., but smaller; tegmina much less maculated and shaded; apical area $1=3$ in length, not longer than 3 as in P. Bergi; breadth of apical area $8=$ length of 7 , not broader as in $P$. Bergi.

## Genus Tympanoterpes.

Tympanoterpes, Stâl (part.), Ann. Soc. Ent. Fr. (4) i. p. 614 (1861); Hem. Afr. iv. p. 7 (1866).
Type, T. serricosta, Germ. (Cicada).
Ot the species Stal originally stated were representative of his genus Tympanoterpes, he subsequently (in 1864) removed a no small proportion to his genus Proarna. The Cicada serricosta, Germ., must be taken as the type.

## Tympanoterpes alboapicata, sp. n.

Head, pronotum, and mesonotum olivaceous green; head with front (excluding central fascia), area of the ocelli, and imner margins of eyes black; pronotum with two central longitudinal black lines, which are much obliquely reflected both anteriorly and posteriorly, and with two small black spots near their base, the incisures fuscous; mesonotum with four large black obconical spots, the two central smallest, and all narrowly margined with ochraceous, a large black spot in front of cruciform elevation which is ochraceous; abdomen brownish olivaceous, bases of segments black, greyishly pilose on each lateral area near base, and with a cretaceous spot on each side of apical segment; body beneath and legs brownish olivaceous; sternum thickly greyishly pilose ; a black fascia between face and eyes ; ventral lateral margins more or less cretaceously tomentose; tegmina and wings pale hyaline; tegmina with the costal membrane and area and basal half of venation olivaceous, apical half of venation, upper half of basal cell, and claval area fuscous; wings fuscous at base, venation either olivaceous or fuscous. Head (including eyes) about equal in width to base of mesonotum, eyes not protuberant; vertex of head at area of ocelli very little longer than frout; posterior pronotal angles angularly lobate; abdomen short, broad, about as long as space between apex of head and base of cruciform elevation.
Long., excl. tegm., ot $^{7}$ ㅇ $23-24 \mathrm{~mm}$.; exp. tegm. 77 mm . Hab. Argentina (Wagner, Brit, Mus.).

## Ollanta, gen. nov.

Head (including eyes) broader than base of mesonotum, eyes projecting beyond anterior angles of pronotum, vertes at area of ocelli about or almost as long as front; pronotum shorter than mesonotum, its posterior angles lobately produced, its lateral margins obliquely narrowed anteriorly, very slightly sinuate; mesonotum moderately convex ; abdomen short, about as long as space between apex of head and base of cruciform elevation, tympanal coverings large, their apices subacute, anteriorly but not interiorly covering cavity; rostrum reaching posterior coxe ; opercula small, transverse, only about reaching base of abdomen; face moderately globose; tegmina and wings hyaline, the first with eight apical areas.

A genus intermediate between Proarna and Selymbria.
Type, O. mexicana, Dist.
Ann. \& May. N. Hist. Ser. 7. Vol. xv.

## Pacarina, gen. nov.

Head (including eyes) broader than base of mesonotum ; eyes projecting beyond anterior angles of pronotum; vertex at area of ocelli much longer than front; pronotum with the posterior angles moderately lobately produced, its lateral margins oblique, slightly sinuate, its length shorter than that of mesonotum ; abdomen about as long as space between apex of head and base of cruciform clevation; tympanal covering3 distinct but inwardly concavely narrowed and exposing the tympanal cavities ; face convex, a little broader than the space between it and eyes; opercula about reaching base of ablomen, their lateral margins oblique, their posterior margins a little rounded; anterior femora armed with two strong spines beneath; rostrum about reaching the posterior coxæ; tegmina and wings hyaline; apical areas eight.

Type, P. signifera, Walk. (Cicada).

## Ariasa, gen. nov.

Head (including eyes) wider than base of mesonotum, the eyes projecting beyond anterior pronotal angles, vertex at area of ocelli as long as or a little shorter than front ; posterior angles of pronotum more or less sublobately produced; abdomen about as long as space between apex of head and base of cruciform elevation ; tympana largely exposed, the flaps only upwardly developed on the lateral areas; face large and globose; rostrum reaching the posterior coxa; opercula short, not passing base of abdomen; abdomen beneath prominently chamnelled at each lateral margin; tegmina and wings hyaline, the first with eight apical areas, basal cell a little longer than broad.
'Iype, A. colombix, Dist. (Tympanoterpes).

## Ariasa nigrovittata, sp. n.

ㅇ. Body above black; head with basal margin and a longitudinal fascia to front, lateral and apical margins of vertex, and an oblique fascia extending from posterior margins of cyes to near ocelli, ochraceous ; pronotum with the anterior margin narrowly, the lateral and posterior margins broadly, ochraceous, each lateral area somewhat castaneous, the posterior angles black; mesonotum with two obconical spots, the margins of which are pale castaneous, a lateral fascia and the cruciform elevation of the same colour, the anterior prolongations of the last more or less shaded with
black; posterior abdominal segmental margins pale castaneous; body beneath and legs brownish ochraccous; base of face, a transverse fascia between face and eyes, apex of rostrum, and bases of ventral segmental margins, black; tegmina and wings pale hyaline; tegmina with the venation, basal cell, and claval area black; costal membrane and area, about inner half of basal cell, longitudinal veins to lower ulnar area, and oblique vein at apex of radial area pale ochraceous; wings with the venation black, basal area piceous, some of the longitudinal veins on basal area pale ochraceous, and the apical half of the abdominal area pale lacteous. The body beneath and legs are thickly and finely ochraceously pilose; head (including eyes) considerably broader than base of mesonotum; eyes projecting beyond anterior angles of pronotum; posterior pronotal angles lobately produced.

In a second female specimen from Bolivia the colour of the body above is paler, inclining more to ochraceous or pale castaneous than black.

Long., excl. tegm., of 25 mm . ; exp. tegm. 83 mm .
Hab. Central Brazil: Chapada (Robert, Brit. Mus.) ; Bolivia (Steinbach, Brit. Mus.).

Allied to A. albiplica, Walk.

## Genus Fidicina.

Fidicina, Amy. \& Serv. Hist. des Hém. p. 472 (1843).
Type, F. mannifera, Fabr. (Tettigonia).
Fidicina Roberti, sp. n.
$\sigma^{7}$. Head, pronotum, mesonotum, cruciform elevation, and body beneath brownish ochraceous; abdomen above black; legs pale castaneous; body ochraceously pilose ; head with the area of the ocelli indefinitely extending on each side towards eyes, and margins of front, black; pronotum with the anterior margin, the incisures, and a narrow central transverse spot in front of posterior margin, black; mesonotum with four obconical spots, the two central shortest, and one on each lateral area longest, a large triangular spot in front of cruciform elevation, with a small rounded spot on each side and two similar spots in front of it, black ; posterior margins of abdominal segments above obscurely castaneous, those of the first and sixth segments more prominently so ; face (excluding base), fascia between face and cyes, spots to coxe and trochanters, and apex of rostrum, black; tegmina
and wings pale hyaline; tegmina with the venation fuscous, costal membrane and area, basal cell, and inner longitudinal vein to basal ulnar area pale green, claval area bright ochraccous, preceded by picous shadings; wings with the venation apically fuscous brown, green towards base; extreme apical area bright ochraceous, streaked with piceous.

Head (including eyes) about equal in width to base of mesonotum, much deflected in front of eyes; abdomen in male very short, about as long as space between apex of head and middle of mesonotum ; tarsi two-jointed; body beneath and legs much more thickly and longly pilose than above; rostrum reaching the posterior coxæ; lateral margins of pronotum centrally moderately sinuate ; opercula transverse, water angles a little posteriorly prolonged, posterior margins concave, lateral margins convex.

Long., excl. tegm., ơ 27 mm . ; exp. tegm. 107 mm .
Hab. Central Brazil: Chapada (A. Robert, Brit. Mus.).

## Fidicina lacteipennis, sp. n.

ठ. Body above brownish ochraccous, abdomen a little darker and somewhat densely ochraceously pilose; head with a transverse fascia extending through area of ocelli, a transverse linear spot on each side of front, and inner margins of eyes, black; pronotum with the in:cisures piceous brown ; mesonotum with four ill-defined macular obconical spots, of which the two central are shortest, and with two small indented piceous spots in front of cruciform elevation; basal segmental abdominal margins moderately piceous; body beneath densely griseously pilose; face and legs ochraceous; rostrum ochraceous, its apical half black; tegmina and wings hyaline, with a creamy-white suffusion, extreme bases of both ochaccous with some piceous markings; tegmina with the veins piccous, those at basal area, the basal cell, and costal membrane and area ochraceous; wings with the veins piceous, at the basal area ochraceous. Head (including eyes) slightly wider than base of mesonotum; length of head about half the width between eyes and much shorter than pronotum, which is almost as long as mesonotum ; cruciform elevation anteriorly truncate, without produced anterior angles; rostrum extending midway between intermediate and posterior cosæ; anterior femora armed with two strong spines beneath.

Lorig., excl. tegm., of 29 mm . ; exp. tegm. 94 mm .
Hab. Amazons (Brit. Mus.).

## Fidicina flavibasalis, sp. n.

f. Body above olivaceous; head with the area of the ocelli, a transverse fascia between eyes, inner margins of eyes, and a narrow posterior margin, black; pronotum with two central anterior and two central posterior spots and the central incisures black; mesonotum with four obeonical spots, the two central shortest, a lanceolate spot in front of cruciform elevation, and a small rounded spot at each of its anterior angulations, black; abdomen with the basal segmental margins black and with the lateral areas of the second and third segments greyishly pilose; head beneath and sternum piceous, greyishly pilose; face, a fascia between face and eyes, rostrum, coxæ, and legs virescent ; abdomen beneath brownish ochraceous; tegmina and wings hyaline, basal areas of both and costal membrane of the first reddish ochraceous; venation fuscous, except at bases, where it is greenish. Head (including eyes) about as wide as base of mesonotum; lateral margins of pronotum moderately oblique and finely hirsute; anterior femora with two strong spines beneath ; tarsi two-jointed.

Long., excl. tegm., \& 20 mm . ; exp. tegm. 65 mm .
Hab. Ecuador: Cachabé (Rosenberg, Brit. Mus.).

## Genus Hemisciera.

Hemisciera, Amy. \& Serv. Hist. des Hém. p. 466 (1843).
Type, H. maculipennis, Lap. (Cicada).
Hemisciera Durhami, sp, n.
Body above brownish ochraceous; lateral and posterior marginal areas of pronotum and sixth and anal segments of abdomen stramineous; head with the lateral margin of front and a broken transverse fascia between eyes black ; pronotum with a narrow pale ochraceous anterior margin and black incisures; mesonotum with four large obconical black spots, of which the two central are shortest, and a small black spot in front of each anterior angle of the basal cruciform elevation ; basal margins of abdominal segments piceous; body beneath and legs paler and thickly greyishly pilose; tegmina with about basal third opaquely virescent ochraceous, remainder pale creamy talc-like, the venation on apical two thirds and costal membrane and area fuscous brown ; wings with almost basal half pale ochraceous, the venation on apical hall fuscous brown. Head (including eyes) much wider than base of mesonotun, the eyes semistylate; pronotum about as wide
as mesonotum; rostrum passing the intermediate cosæ; anterior femora with a long subapical spine beneath; tarsi two-jointed; opercula in male transverse, posteriorly rounded, not extending beyond base of abdomen.

Long., excl. tegm., す 33 mm . ; exp. tegm. 100 mm .
IIab. Brazil : Para (Dr. II. E. Durham, Brit. Mus.).

## Majeorona, gen. nov.

Ilead (including eyes) considerably broader than base of mesonotum ; eyes protuberant, more or less stylate ; length of head above about equal to half its breadth between eyes and about or almost as long as pronotum, which is distinctly shorter than mesonotum; abdomen about as long as space between apex of head and base of cruciform elevation; the tympanal orifices exposed interiorly, the flaps almost as long as and covering the lateral areas, not prominently concave interiorly; metasternal plate well developed, centrally longitudinally impressed and anteriorly produced on each side; rostrum reaching the posterior coxa; anterior femora strongly spined beneath; tarsi three-jointed ; opercula in male small, transverse, not extending beyond base of abdomen; tegmina and wings hyaline, the first with eight apical areas and the basal cell longer than broad.

Type, M. aper, Walk. (Fidicina).

## Majeorona bovilla, sp. n.

万. Body above black; head with the apical margin of front, lateral margins of vertex, and inner margins of eyes angularly continued to near area of ocelli, olivaceous brown; pronotum with the anterior margin narrowly and the lateral and posterior margins broadly stramineous (the lateral margins outwardly black), and with a more obscure small discal spot of the same colour; mesonotum with the margins of two central obconical spots and the cruciform elevation pale castanecus; abdomen above with its lateral margins and the posterior margins of the segments pale castaneous; body beneath and legs ochraceous; central sulcation and lateral margins of face, a fascia between face and eyes, and apices of anterior and intermediate femora, black; tegmina and wings pale hyaline, the bases of both black, mottled with brownish ochraceous, and divided by pale ochraceous veins; tegmina with the costal membrane and area black, basal cell black, with a basal central ochraceous sjot, venation black, ochraceous at extreme base, transverse veins at bases of second and third apical areas a little infuscated; wings with the
lower half of venation ochraceous, the upper half black. Head (including eyes) considerably broader than base of mesonotum ; eyes protuberant, moderately stylate ; length of head about half its width between eyes and almost as long as pronotum, the lateral angles of which are rounded; basal areas of cruciform elevation strongly obliquely striate; opercula transverse, not passing base of abdomen; anterior femora strongly spined beneath.

Long., excl. tegm., of 43 mm .; exp. tegm. 127 mm .
$H a b$. Central Brazil: Chapada, 2600 feet (A. Robert, Brit. Mus.).
XXXVII.-The Changes and Variations in the Position of the Pectoral Fin during Development. By H. H. Sifinnerton, D.Sc., University College, Nottingham.

For some time I have been investigating the development of the Teleostean pectoral fin skeleton *. This has brought into my hands an extensive series of developmental stages of the three-spined stickleback (Gasterosteus aculeatus). Being struck by the difference in the relative positions of the fin in the youngest and oldest stages, I measured numerous specimens of all ages, with a view to ascertaining definitely if this indicated a real shifting during development.

The investigation above referred to brings out the fact that the glenoid border tends to rotate from a horizontal to a vertical position during development. This rotation is around the ventral end of the border. Consequently this point seemed the most suitable one from which to take measurements. 'Two were taken in each case, viz. from this point to the tip of the snout and to the hinder extremity of the notochord.

In fig. 1 (p. 320) the vertical line represents the distance of the pectoral fin from the tip of the snout, the horizontal that from the extremity of the notochord. The oblique lines give the average position of the fin at various stages. To obtain these the specimens were put together into groups containing individuals differing in length only 1 mm ., and the average was found for each group. Gaps are left because the material proved insufficient to give trustworthy results at these points.

The shortest line represents the average position of the fin

[^35]for 97 individuals varying in length from 4.5 to 6.5 mm . and in age from the time of hatching to the end of the third week. This is prolonged by a dotted line, to give an idea of the course it would have taken had there been no translocation later.

Fig. 1.
The next line represents the average position of the fin for 198 individuals varying in length from 10.4 to 15.6 mm . The age of these camot be definitely stated, because they were not reared in the aquarium and individuals of the same age vary so greatly after the first month*. The position of this line relative to the dotted line and its increasing divergence from it show that the fin has shifted backwards and is continuing to shift.

The longest line represents the average position for 211 individuals varying in length from 25 to 50 mm ., and exhibits the same facts more markedly.

Figs. 2, 3, and 4 were made from measurements of individuals varying in size from 4 to 7, 10 to 16, and 25 to 50 mm . respectively. The horizontal line represents the distance from fin to snout expressed as a percentage of the total length of the body. The rertical lines give the number of individuals with the corresponding percentage. From these it is seen that the maximum number have their fins 23 per cent. from the snout in the first group, 33 per cent. in the second,

* For example, of the two oldest specimens which I hatched and lept in the same aquarium for thirty-three days, one measured 10.8 mm , and the other only 6.4 mm .
and 39 per cent. in the last. Judging by these maxima, therefore, there is a total translocation of 16 per cent. of the length of the body. It is interesting to note that if the fifty smallest sticklebacks are taken the maximum falls upon the 22 per cent. line.

Fig. 2.
Fig. 3.
Fig. 4.
The immediate cause of the shifting of the fin is to be found in the fact that the coraco-scapular plate is at first a very insignificant portion of the pectoral skeleton, but as development advances it broadens out antero-posteriorly.

The ultimate cause may be the change in function of the pelvic fin from that of a true fin to that of a mere organ for attack or defence. The pectoral fin has therefore to perform the combined functions of the two pairs.

In view of the phylogenetic shifting forwards of the pelvic fin in Teleosts, it would be instructive if some worker with a large series of types at his disposal would ascertain if there is a corresponding phylogenetic shifting back of the pectoral fin. At present I can find no explanation of the fact that the fin shifts most rapidly just at those points in the ontogeny where my collection of specimens is poorest.

A further study of figs. 2-4 suggests that the range of variation in the position of this fin increases as life alvances. In the first group the range is 8 per cent., in the sccond 9 per cent., in the third 13 per cent.

## XXXVIII.-A new Cricetulus from Mongolia. By Oldfield Thomas.

Among a small collection of rodents from N.E. Siberia presented to the National Museum by Mr. C. W. Campbell there are two specimens of a Cricetulus which appears to be undescribed. It may be called

## Cricetulus Campbelli, sp.n.

Closely allied to C. songarus, Pall., which alone of described species has completely hairy palms and soles. Colour and markings apparently much as in that species, the characteristic light patches on shoulders, sides, and hips contrasting prominently with the body-colour, but the dark shoulderstripe of $C$. songarus is less developed and the dorsal line is narrower and more sharply defined. Back greyish buffy ; a prominent black dorsal line commencing faintly on the crown, becoming sharply defined on the nape, and running to the base of the tail. Lateral patches creamy buff, the grey areas dividing them but slightly darkened. Belly-hairs slaty basally, "cream-buff" terminally. Ears small, much smaller than in the true C. songarus; their colour as described in C. dichrootis, Satunin *, the black of the front half of the outer surface contrasting markedly with the white of the hinder edge of the inner. Upper surface of hands and feet silvery white. Palms densely hairy, but the tips of the digits, the usual three small pads at the base of the fingers, the very large hallucal and small median carpal pads naked. Similarly, behind, the soles are densely hairy, the tips of the digits and three small distal pads alone naked. Tail very short, about half the length of the hind foot, club-shaped, silvery whitish.

Skull short, the brain-case proportionally large and rounded. Palatal foramina parallel-sided. Bullæ very small.

Dimensions of the type (measured as a spirit-specimen) : -
Head and body 87 mm. ; tail 7 ; hind foot 12 ; ear 11.
Skull: greatest length 24 ; basilar length 19; zygomatic breadth 13.7 ; length of nasals 9 ; interorbital breadth 3.7 ; breadth of brain-case $11 \cdot 4$; palate length 9.8 ; diastema 6.4 ; palatal foramina $4.1 \times 1 \cdot 6$; length of upper molar series 3.5 .

IIab. Shaborte, N.E. Mongolia (about $46^{\circ} 40^{\prime}$ N., $114^{\circ}$ E.). A second specimen from Thatir Suma.
Type. Male (skinned out of spirit). B.M. no. 5. 2. 1. 3.

[^36]Collected 1st July, 1902, and presented by C. W. Campbell, Esq., C.M.G.

This very handsome little species seems alone allied to C. songarus, Pall., and C. dichrootis, Sat., but may be readily distinguished from the former by its smaller ears and rather different colour, and from the latter by its more completely hairy soles and its prominent dorsal line.

## XXXIX.—The Affinities of the Orkney Vole (Microtus orcadensis, Millais). By C. I. Forsyth Major.

In a joint paper by Mr. Eagle Clarke and Professor Charnock Bradley are published some new and interesting observations on the Orkney vole discovered by Mr. Millais in the Orkneys and certain parts of Shetland \%. I have had an opportunity to verify the accuracy of the facts communicated, but I venture to take exception to the interpretation given to these facts, as being intended to throw light on the affinities of the species. By representing the Orkney vole as being in some respects an intermediate form of the field- and the water-vole, but more nearly allied to the latter, a misleading conception of its true affinities is conveyed.

The two British species just mentioned are so widely apart from each other that they have been placed into two distinct sections (subgenera) of the genus Microtus. Now the Orkney vole, by its external characters (number of foot-pads on the hind sole, absence of abdominal musk-glands), as well as by the character of its teeth, is clearly a member of the same subgenus as the field-vole, and therefore much nearer related to the latter than to the water-vole. The peculiarities of its skull by no means contradict this statement. Great width of the skull, relative shortness of the brain-case, and elongation of the rostrum, are not peculiarities proper to the water-vole alone; they occur in other subgenera also. Within the subgenus to which our common field-vole (1.. agrestis) belongs it is the M. arvalis and its allies, one of the field-voles of Continental Europe and Northern Asia, which the Orkney vole approaches most in the characters of

[^37]the skull. The teeth of the last-mentioned being, moreover, indistinguishable from those of the 1\%. arealis group, I would assign it a place within the latter, of which it is a largesized and otherwise remarkable form, well deserving of a specific name of its own.

One form (possibly more) of a vole with teeth of the M. arvalis type is represented by jaws in some of our caves and river-deposits. Not having as yet come upon fairly complete skulls, I do not venture to assert that the species M. arvalis was represented in Great Britain during Pleistocene times; but the M. arvalis group certainly was. This last circumstance will in due time presumably help to explain satisfactorily the present existence of a member of the M. ar$\boldsymbol{v}$ alis group in the Orkney and Shetland Islands.
> XL.-Description of a new Leucania from British New Guinea. By George T. Bethune-Baker, F.L.S., F.Z.S.

## Leucania diagramma, sp. n.

ठ. Head and face pale grey, barred with dark grey ; collar pale grey, barred with darker grey; thorax greyish; patagia edged on its upper margin with dark grey ; abdomen greyish ; legs pale grey, mid and hind pair with two fine dark laterd lines. Primaries greyish brown, covered with fine whitishgrey longitudinal lines, with a broad pale stripe in the cell and a broader one below the cell; a dark spot at the lower end of the cell; a postmedial row of small dark spots, on the interior of which is a transverse indefinite band of whitish grey; termen darkly spotted: secondaries greyish, paler towards the base. Uuderside: primaries pale grey, with the dark lines of the upperside showing through; a dark costal spot a quarter from the apex; termen finely and darkly dotted : secondaries whitish grey, finely irrorated on the costa with dark scales; termen darkly spotted.

Expanse 38 mm .
The type is in my collection from Babooni, British New Guinea (3600 feet), where it flies in September.
XLI.-Description of a new Fish of the Genus Dentex from the Coast of Angola. By C. 'Tate Regan, B.A.

## Dentex Cuninghamii.

Depth of body $2 \frac{2}{3}$ in the length, length of heal 3. Snout scarcely longer than eye, the diameter of which is $3 \frac{1}{2}$ in the length of head and $1 \frac{1}{4}$ in the interorbital width. Depth of preorbital $\frac{2}{3}$ the diameter of eye. Maxillary nearly reaching the vertical from anterior margin of eye; canines rather weak, 3 or 4 on each side in the upper jaw, 5 or 6 on each side in the lower. Cheek with 6 series of scales. 10 gill-rakers on the lower part of the anterior arch. Scales $60 \frac{6}{14}$. Dorsal XII 10, the spines slender, the fourth and fifth the longest, equal to $\frac{1}{2}$ the depth of body; soft rays as long as the eye. Anal III 10, the third spine a little longer than the second, as long as the eye. Pectoral $1 \frac{1}{5}$ the length of head, extending to above the third soft ray of anal ; ventrals extending: to the vent. Caudal widely forked. Olivaceous above, silvery below; each scale of the upper and posterior parts of the body appears to be reddish at the base and blackish at the edge.

A single specimen, 220 mm . in total length, from the coast of Angola, collected and presented to the British Muscum by R. J. Cuninghame, Esq.

## BIBLIOGRAPHICAL NOTICES.

Two Cytological Works.
Motricr (Dirid M.). Fecundation in Plents. Washington (Carnegie Institution), 1904. 8vo. Pp. viii, 187. 69 figs. in text. Ferguson (Margaret C.). Contributions to the Knowledge of the Life-history of Pinus, with Special Reference to Sporogenisis, the Development of the Gametophytes, and Fertilization. Washington, Proc. W. Acad. Sc. vol. vi. pp. 1-202, pls. i.-xxir. [i. e. pp. 1$154,15 \tilde{6}-202$ verso only, facing plates].
The extreme interest and importance of the subject of these two works have created a copious literature and incited many workers in the field of research. Dr. Mottier has performed a useful task in presenting a digest of the subject, chiefly dealing with the Cryptogams and Gymnosperms, the Angiosperms being dismissed in a dozen pages. The subjects of the seven chapters will give a clue to the scheme of treatment ; they are as follows:-1. Introduction, in which nuclear division is explained and illustrated; 2. Fecundation by motile isogametes, 3. by non-motile isogametes, 4. by heterogametes; 5. Ascomycetes and Rhodophycea; 6. Archigoniate: and 7. Angiosperms.

A few slips have been noticed in looking through the pages, as Tulipe Celliana (p. 178) for Celsianc, Alexander Brown (p. 61) for Braun; on page 67 a given figure, E , is assigned to two different authors; on page 102 " nearly amoboid parasites" should, of course, be mertly, and Synchitrium decipiens, Fries, appears as "discipens" (p. 37), \&c.

Dr. Margaret Ferguson's paper is given up to a detailed account of her researches on a topic on which she has already published good work. The different scale of the two works now under notice may be gauged by the fact that here 141 pages are devoted to what is compressed into less than 6 pages of Dr. Mottier's paper.

In both the modern slipshod method of reference to literature is employed, namely, that of giving the author and an abbreciation for the year, as ( 01 ) for 1901. It is a real grievance that if these references are to be checked the page is not supplied also, for the plan here followed is that of flinging a bulky paper at the reader and bidding him discover for himself where the statement cited is to be found. It is this easy writing that makes hard reading, and those who have been trained in an older and perhaps more careful school, revolt at this offhand method, now too much in vogue.

# PROCEEDINGS OF LEARNED SOCIETIES. 

GEOLOGICAL SOCIETY.
November 9th, 1904.-J. E. Marr, Sc.D., F.R.S., President, in the Chair.
Mr. E. T. Melvton, in exhibiting, by permission of the Director of H.M. Geological Survey, a specimen of Fayolia near to Fayolia grandis, found by Dr. L. Moysey of Nottingham in the CoalMeasures of Ilkeston (Derbsshire), pointed out that Fayolia was first described by Profs. Renault \& Zeiller in 1884, in their monograph on the 'Houiller de Commentry.' In 1894 Mr. Seward described the first British specimen, from Northumberland, in the Leeds 'Naturalist,' but thought that it was not a plant. There was some resemblance to certain spiral egg-casos of Elasmobranchs; but Dr. Giinther was unwilling to accept the Northumberland fossil as the egrg-case of a fish. Mr. Kidston had not yet seen the specimen now exhibited; but, from a sketch, he recognized its relation to Fayolia. At present, there was still uncertainty as to the exact nature of this fossil.

The following communications were read:-

1. 'Notes on Upper Jurassic Ammonites, with Special Reference to Specimens in the University Museum, Oxford : II.' By Miss Maud Healey.

This paper gives a redescription of the types of Cardioceras vertebrale, Sow., C. scarbrugense, Y. \& B., C. cordatum, Sow., and
C. excavatum, Sow., and their varieties. Four varieties of the first, nine of the second, three of the third and fourth, are defined, and a description is given of a new species of Cardiocerus belonging to tho same group. Notes on species allied to the group and on others which have been wrongly confused with it are added. These species are so closely connected by innumerable transitional forms that their limits cannot be definitely fixed. The term 'species' is therefore used as equivalent to Prof. J. W. Gregory's circutus: 'It includes a number of "forms," which rary aloug lines radiating outward from a central type. Some of the members farthest removed from the centre may be within the range of another circulus, for the different circuli may overlap or be connected by an indefinite series of individuals.' Each circulus is made up of subcirculi or varieties, and several circuli make up a group which need not necessarily correspond with a genus. C. cordatum is retained as the name of the whole group, although the type is a most unsatisfactory little specimen from the Corallian of Shotover.
2. 'On the Occurrence of Elephas meridionatis at Dewlish (Dorset). Second communication: IIuman agency suggested.' By the Rev. Osmond Fisher, M.A., F.G.S.

This paper is in continuation of one published by the Author in 1888. The site in which the elephant-remains were found is a narrow trench, examined to a depth of 12 feet in places, with nearly-vertical sides, a smooth, chalk-bottom, and an abrupt end. It was not a fault or a stream-course, and it was partly filled with fine dust-like sand which may have been wind-borne. The trench cuts diagonally across the scarp; and, even if it could be accounted for by natural agencies, it is difficult to explain how it happened that so many elephants fell into it. The Author points out that in Africa elephants are caught by the natives in pitfalls of similar character coustructed on the tracks leading to watercourses. This trench is in a corresponding position with regard to a stream, and it is suggested as possible that the trench may have been of human origin. There is, however, no conclusive evidence elsewhere that man was contemporary with Eiephas meridionalis, which is characteristic of the Pliocene Age.

> Norember 23 rd, $1904 .-\mathrm{J}$. E. Marr, Sc.D., F.R.S., President, in the Chair.

The following communication was read:-
' On an Ossiferous Cavern of Pleistocene Age at Hoe-Grange Quarry, Longcliffe, near Brassington (Derbyshire).' By Henry Howe Arnold-Bemrose, M.A., F.G.S., and Edwin Tulley Nowton, F.R.S., V.P.G.S.

During quarrying-operations in Hoe-Grange limestone-quarry in April 1902 the workmen broke into a cavern. The discovery was
first made knorn to the mriters by Mr. J. Ward, of the Cardiff Museum, but the news of mammalian bones being found soon spread, and many of the remains were carried away. An arrangement to work the cave systematically was made, with the permission of the owner, Major Nicholson, and it has now been entirely worked out, the results being given in the present paper.

The quarry is situated near the top of the plateau, at about 1100 feet above Ordnance-datum. The care is evidently a masterjoint in the limestone, enlarged by water, and, besides being a swallow-hole, has served as a hyæna-den. The large number of mammalian remains found includes lion, hyæna, rhinoceros, Elephas, and other Pleistocene forms; but, besides these, there were numerous bones and teeth of fallow-deer, mixed with the Pleistocene remains at all horizons in the eave. The physical conditions are such as to preclude, as the Authors think, any idea of a redeposition of the bones at any date subsequent to the Pleistocene Period; and it is concluded, therefore, that the fallow-deer (Cerus clama) was a Pleistocene species, although hitherto supposed to be a much later introduction.

## MISCELLANEOUS.

## On Chelonethi. By C. J. Witi, Copenhagen.

Br an orersight, which I greatly regret, the names Chelifer punctatus, Keys., and Ch. brevidigitatus, Keys., have been confused in my paper "On Chelonethi \&c." in the January number of the 'Annals.' I have not examined Ch. brevidigitatus, as stated on p. 112, but Ch. punctatus; the former species is not in the collections of the British Museum, only the latter. The remarks on "Chelifer brevidigitatus, Keys. 1885 (3), pp. 48-49, tab. is. figs. 6-6 c," consequently refer to Ch. punctatus, Keys. 1855 (3), pp. 45-46, tab. iv. figs. 3-3 c.

0 wing to the same confusion of the names, " $a^{17}$ and $b^{17}$ " in the synopsis ( p .97 ) must be altered to

$$
\begin{aligned}
& a^{17} \text {. Ilairs of the tergites within a } \\
& \text { brevidigitatus, Keys. }
\end{aligned}
$$

An indistinctly written Museum label caused the locality for Ideoroncus mexicinus, Bks., to be wrongly given on p. 130. It should be "Chantilly, Windward side of Grenada, West Indies." On p. 139, fourth line from bottom, for "sternite" read "segment."

## THE ANNALS

# magazine of natural history. <br> [SEVENTH SERIES.] 

No. 88. APRIL 1905.
XLII.-A Revision of the Fishes of the South-American Cichlid Genera Acara, Nannacara, Acaropsis, and Astronotus. By C. Tate Regan, B.A.
The Cichlidæ have recently been monographed by Pellegrin (Mém. Soc. Zool. France, xvi. 1904), who has dealt in a most interesting manner and at considerable length with their anatomy and with the biological problems which they present. However, I have arrived at somewhat different conclusions as to the distinction and arrangement of species in certain genera, which must be my excuse for the present paper.

The genera here dealt with are distinguished from other American Cichlidæ by the following combination of characters :-Dorsal fin without notch betwcen spinous and soft portions; gill-rakers short, in small or moderate number ; anal fin with 3 spines; tecth conical; preoperculum entire; no lobe on the anterior branchial arch. Their relations to each other may be shown thus:-

> I. Soft vertical fins scaleless or scaly at the base only. D. XIII-XVI 7-12; A. II 6 -11. A. Maxillary not exposed; premaxillaries moderately protractile. Upper laterai line well separated from dorsal fin ........ Acara. Upper lateral line separated from dorsal fin by only $\frac{1}{2}$ an series of scales for most of its length. ........... Narnacara. B. Maxillary exposed; premaxillaries very protractile. Acaropsis.
II. Soft vertical fins covered with small scales; D. XII-XIV 19-21; A. III 15-16

Astronotus.
Ann. \& Mag. N. Hist. Ser. 7. Vol.xv. 23

I have given a list of the specimens in the British Museum on which my descriptions are based, with the total length of each in millimetres.

## Acara.

Acara (part.), IIeck. Ann. Mus. Wien, ii. 1840, p. 338; Giunth. Cat.
Fish. iv. p. 276 (1862) ; Steind. Sitzb. Ak. Wien, lxxi. 1875, p. 63. AEquidens *, Eigenm. \& Bray, Ann. Ac. N. York, vii. 1894, p. 616. Acara, l’ellegr. Mém. Soc. Žool. Frauce, xvi. 1903, p. 171 (1904).
Body deep or moderately elongate, compressed; scales large, usually fincly etenoid. Two lateral lines, the upper well separated from the spinous dorsal. Mouth small or moderate ; premaxillaries moderately protractile; maxillary not exposed distally ; jaws with small conical teeth in bands, those of the outer series more or less enlarged ; upper surface of head scaly to between the orbits; cheeks and opercular bones scaly; præoperculum entire. Gill-rakers few and short; no lobe on the upper part of the anterior branchial arch. A single dorsal, with XIII-XVI 7-12 rays; aual with III 6-11 rays ; soft dorsal and anal scaleless or scaly at the base; caudal truncate or rounded. Pectoral asymmetrical, with 12-15 rays; ventrals below or a little behind the base of the pectoral.

Eighteen species from S. America, extending into Panama.

## Skeleton.

In $A$. tetramerus the supraoccipital crest is high and extends forwards on the frontals, which are hollowed out anteriorly to form the posterior margin of the depression in which the premaxillary processes lie. The latter are rather short, extending nearly to above the orbit; the parietal crests are moderately strong and extend to abore the middle of the orbits. There are 26 vertebræ $(13+13)$; parapophyses are developed on the precaudal vertebræ from the fourth; the ribs are subsessile. The fourth vertebra bears a pair of feeble inferior apophyses. The lower pharyngeals are united by a straight suture.

[^38]This genus is scarcely distinct from the African Paratilapia, which differs in having the maxillary more or less exposed distally and in the constantly smaller size of the scales of the thoracic region. The distinction between Acar $\ell$, with 3 anal spines, and Cichlosoma, with 4 or more anal spines, is somewhat arbitrary, but convenient.

## Synopsis of the Species ${ }^{1}$.

I. Præoperculum scaleless.
A. Dorsal and anal fins scaleless.

1. Depth of body $2-2_{5}^{2}$ in the length.
a. 5 or 6 gill-rakers on the lower part of anterior arch.

* 2 or $2 \frac{1}{2}$ scales between lateral line and anterior rays of soft dorsal. D. XILI-XVI 9-11. A. III 8-10.

1. tetramerus.

* 1 or $1 \frac{1}{2}$ scales between lateral line and anterior rays of soft dorsal.
$\dagger$ Dorsal spines subequal from about the fourth to the twelfth. D. XIII-XV 10-11. A. III 6-8.
$\ddagger$ Caudal peduncle from $\frac{3}{4}$ to as long as deep.
Depth of body $2-2 \frac{1}{3}$ in the length; middle dorsal spines more than $\frac{2}{5}$ the length of head......
Depth of body $2 \frac{1}{3}-2 \frac{2}{5}$ in the length; middle dorsal spines usually less than $\frac{2}{5}$ the length of head.

2. vittata.
$\ddagger \ddagger$ Caudal peduncle $\frac{1}{2}-\frac{2}{3}$ as long as deep.
3. paraguayensis.
$\dagger \dagger$ Dorsal spines increasing in length throughout; caudal peduncle $\frac{1}{2}-\frac{2}{3}$ as long as deep.

## 1. Acara tetramerus.

Acara tetramerus, Heck. Ann. Mus. Wien, ii. $1840, \mathrm{p} .3+1$; Giinth. Cat. Fish. iv. p. 277 (1862) : Steind. Sitzb. Ak. Wien, lxxi. 1875, p. 65 ; Cope, Proc. Ac. Philad. 1872 , p. 255 , and Proc. Am. Phil. Soc. xxxiii. 1894, p. 106 ; Pellegr. Mém. Soc. Zool. France, xri. 1903, p. 171 (1904).
Acara viridis, Heck. t. c. p. 343 ; Günth. t. c. p. 280.
Acara diadema, Heck, t. c. p. 344.
Acara pallidus, Heck. t. c. p. 347 ; Giinth. t. c. p. 280.
Chromys muntata, Casteln. Anim. Am. Sud, Poiss. p. 13, pl. viii. fig. 1 (1855).

Chromys uniocellata, Casteln. t. c. p. 15, pl. vi. fig. 1.
Acara vittata (non Heck.), Giinth. t. c. p. 279.
Acara uniocellata, Günth. t. c. p. 281.
Astronotus tetramerus, Eiqenm. \& Eigenm Proc. U.S. Nat. Mus. xiv. 1891, p. 68: Eigenm. \& Bray, Ann. Ac. N. York, vii. 1894, p. 617.
Equidens tetramerus, Eigenm. \& Kennedy, Proc. Ac. Philad. 1903, p. 534.

Depth of body 2-21 $\frac{1}{3}$ in the length, length of head $2 \frac{3}{4}-3$. Snout shorter than postorbital part of head. Diameter of eye $2 \frac{2}{3}-3 \frac{2}{3}$ in the length of head, interorbital width $2 \frac{2}{-2}-2 \frac{3}{4}$. Depth of preorbital $\frac{1}{2}-1 \frac{1}{6}$ the diameter of eyc. Maxillary extending about to the vertical from anterior margin of eye; jaws equal anteriorly; fold of the lower lip not continuous; cheek with 3 or 4 series of scales; preoperculum scaleless; 5 or 6 gill-rakers on the lower part of anterior arch. Scales $25-27 \frac{3-3 \frac{1}{8}}{8-10}$, 2 or $2 \frac{1}{2}$ between lateral line and anterior

$$
\because \text { A. firenifera. }
$$

rays of soft dorsal. Dorsal XIII-XV (XV1) 9-11, commencing above the opereular cleft, the spines subequal from the fourth or slightly increasing in length to the last, which is $\frac{5}{5}-\frac{1}{2}$ the length of head. Anal III 8-10. Dorsal and anal fins scaleless. Pectoral at least as long as the head ; ventral extending to origin of anal or beyond. Caudal rounded. Caudal peduncle $\frac{1}{2}-\frac{9}{3}$ as long as deep. Olivaceous, with 5 dark cross-bars, the first crossing the anterior 7 or 8 scales of the lateral line, the second the 9 th or 10 th and 3 succeeding scalcs of the lateral line, below which it bears a blackish bloteh; a dark spot below the posterior part of eye ; a dark ocellated spot on the upper part of the base of caudal; usually a dark longitudinal band from lateral bloteh to caudal spot, sometimes continued forward to the eye ; vertical fins dusky, usually spotted.
R. Amazon ; Guiana.

## 2. Acara vittata.

Acara rittuta, Heck. Ann. Mus. Wien, ii. 1840, p. 346; Steind. Sitzb. Ak. Wien, 1xxi. 1875, p. 72, pl. iii. fig. 1.
Acara viltata (part.), Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 173 (1904).

Depth of body $21.2 \frac{1}{3}$ in the length, length of head $23-2 \frac{1}{2}$. Snout shorter than postorbital part of head. Diameter of eye $3-3 \frac{3}{4}$ in the length of head, interorbital width $2 \overline{2}-3$. Depth of preorbital about equal to diameter of eye. Maxillary extending nearly to below the anterior margin of eye; jaws equal anteriorly; check with 3 series of seales; preeoperculum scaleless; 6 gill-rakers on the lower part of anterior arch. Scales $24-26 \frac{3}{9}, 1$ between lateral line and anterior rays of soft dorsal. Dorsal XIII-XIV 10-11, commencing above the opercular cleft, the spines subequal from about the fourth to the twelfth, which are more than $\frac{2}{\overline{5}}$ the length of head, the last $\frac{1}{2}$ the length of head; soft fin extending nearly to middle of caudal. Aual III 7-8. Dorsal and anal fius scalcless. Pectoral as long as the head ; ventral extending to origin of anal or beyond. Caudal * rounded or truncate. Caudal peduncle nearly as long as deep. Olivaceous, with obscure darker cross-bars; a dark longitudinal

[^40]band from eye to end of soft dorsal ; a dark vertical stripe below the posterior margin of eye; a dark spot on the upper part of the base of caudal ; vertical fins with dark spots.

Guiana; R. Amazon ; R. Paraguay.
The examples described by Steindachner measure up to about 130 mm . in total length.

## 3. Acara syspilus.

Acara syspilus, Cope, Proc. Ac. Philad. xxiii. 1872, p. 255, pl. xi. fig. 3.
Acara rittata (part.), Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 173 (1904).

Depth of body $2{ }_{3}^{1}-2 \frac{2}{5}$ in the length, length of head 24. Snout a little shorter than postorbital part of head. Diameter of eye $3 \frac{1}{4}$ in the length of head and equal to the interorbital width. Depth of preorbital $\frac{3}{4}$ the diameter of eye. Maxillary extending to the vertical from anterior margin of cye; lower jaw slightly shorter than the upper ; fold of the lower lip not continuous; cheek with 3 series of scales; præoperculum scaleless; 5 or 6 gill-rakers on the lower part of anterior arch. Scales $26-27 \frac{3}{8-9}, 1 \frac{1}{2}$ between lateral line and base of anterior rays of soft dorsal. Dorsal XIV-XV 9-10, commencing above extremity of operculum, the spines subequal from the fourth or fifth to the twelfth or thirteenth, which are $\frac{1}{3}-\frac{2}{5}$ the length of head; last spine from $\frac{2}{3}$ to nearly $\frac{1}{2}$ the length of head; soft fin extending nearly to middle of caudal. Anal III 7 (8). Dorsal and aual fins scaleless. Pectoral as long as the head ; ventral extending to origin of anal or beyond. Caudal subtruncate. Caudal peduncle $\frac{3}{4}-\frac{4}{5}$ as long as deep. Olivaceous, with about 7 darker crossbars and with a dark longitudinal band from eye to end of base of dorsal; a dark vertical stripe below the posterior part of eye; vertical fins dusky, with darker spots, which are most distinct on the soft dorsal.

Upper Amazon.
1-3. ( 95 - 101 mm .) Canelos. C. Buckley, Esq.
I have little doubt that these specimens belong to the species which Cope founded on very young specimens and which appears to differ from $A$. vittuta in the more slender body, longer snout, narrower intcrorbital space, and less elevated spinous dorsal.

## 4. Acara paraguayensis.

Acara parayuayensis, Eigenm. \& Kennedy, Proc. Ac. Philad. 1v. 1903, p. 534 ; Pellegr. Mém. Soc. Zool. France, xri. 1903, p. 17 (1904).

Depth of body $2 \frac{1}{6}-2 \frac{1}{4}$ in the length, length of head $2 \frac{2}{3}-2 \frac{3}{3}$. Snout shorter than postorbital part of head. Diameter of eye $2 \frac{3}{4}-3 \frac{1}{4}$ in the length of head, interorbital width $2 \frac{1}{3}-3$. Depth of preorbital equal to diameter of eye or less. Maxillary extending to the vertical from anterior margin of eye ; jaws equal anteriorly or the lower the shorter; fold of the lower lip not continuous; cheek with 3 series of scales; preoperculum scaleless; 6 gill-rakers on the lower part of anterior arch. Scales $24-26 \frac{21}{8}-3,1$ or $1 \frac{1}{2}$ between lateral line and anterior rays of soft dorsal. Dorsal XIV (XIII-XV) $9-10$, commencing above the opercular cleft, the spines subequal from the fourth to the twelfth, which are more than $\frac{2}{5}$ the length of head, thence slightly increasing to the last, which is $\frac{1}{2}$ the length of head; longest soft rays extending nearly to middle of caudal. Anal III 7 (6-8). Dorsal and aual fins scaleless. Pectural a little longer than the head; ventral estending beyoud origin of anal, sometimes to the posterior end of base of anal. Caudal rounded. Caudal peduncle $\frac{1}{2}-\frac{2}{3}$ as long as deep. Body with about 7 dark cross-bars, the third bearing a large blackish blotch below the seventh to the tenth scales of the lateral line; a dark longitudinal stripe from eye to lateral blotch; a dark vertical stripe below the eye; a dark spot on the upper part of the base of caudal ; soft dorsal with oblique dark stripes or series of spots posteriorly.
R. Paraguay.

2. ( 79 mm .) Descalvados, Matto Grosso. Dr. Ternetz.

3-5. (49-71 mm.) Carandasiñho, Matto Grosso. Dr. A. Borelli.

## 5. Acara pulchra.

Cychlasoma pulchrum, Gill, Ann. Lyc. N. York, ri. 1858, p. 382.
Acara cerruleopunctata, var. latifrons, Steind. Denkschr. Ak. Wien, xxxix. 1879, p. 27.

Acara pulchra (part.), Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 176 (1904).

Depth of body $2 \frac{1}{6}-2 \frac{1}{4}$ in the length, length of head $22^{3}-2 \frac{5}{6}$. Snout shorter than postorbital part of head. Diameter of eye $3 \frac{1}{4}-3 \frac{1}{2}$ in the length of head, interorbital width $21-2 \frac{1}{5}$. Depth of proorbital a little less than diameter of eye. Maxillary extending to the vertical from anterior margin of eve ;
jaws equal anteriorly ；fold of the lower lip not continuous ； check with 3 series of scales；preoperculum scaleless ； 6 gill－ rakers on the lower part of anterior arch．Scales 2t－26 $\frac{3}{8}$ ，l or $1 \frac{1}{2}$ between lateral line and anterior rays of soft dorsal． Dorsal XIII－XIV 9－11，commencing above opercular cleft， the spines increasing in length to the last，which is $\frac{1}{2}$ the length of head；fourth spine 1－言 the length of head ；soft fin pointed，the longest rays extending nearly to the end of caudal．Anal III 7－9．Dorsal and anal fins scalcless． Pectoral a little longer then the head；rentral extending nearly to middle of anal；caudal rounded．Caudal peduncle $\frac{1}{2}-\frac{3}{3}$ as long as decp．Olivaccous，with 7 or 8 dark cross－ bars，the third crossing the 9 th or 10th and succeeding scale of the lateral line and bearing a blackish blotch below the lateral line；a dark vertical bar below the posterior $\frac{1}{2}$ of eye； sides of the head and anterior part of the body with blue spots，some of those on the head confluent to form stripes； fins dusky，the spinous dorsal with about 3 almost longitu－ dinal dark stripes，the soft dorsal with narrow oblique stripes or series of spots；caudal with dark spots．

Colombia；Venezuela；Trinidad．
1－3．（114－125 mm．）Baranquilla，Colombia．Kay Thomson，Esq． 4－6．（10ご－119 mm．）Trinidad．L．Guppy，Esq．

This species has been confounded with $A$ ．ceeruleopunctata， from which it is distinguished by the larger scales，fewer dorsal spines，broader interorbital space，and more produced soft dorsal and anal．

## 6．Acara cerruleopunctata．

Acara corulenpuctata，Kiner \＆Steind．Sitzb．Bayern Ak．1863，p．222， and Abhandl．Bayern Ak．x．1864，p．16，pl．ii．fig． 3 ；Günth．Trans． Zool．Soc．vi． 1869, p． 449.
Equidens cœruleopunctatus，Jord．\＆Everm．Bull．U．S．Nat．Mus．xlvii． 1898，p． 1514.
Acara milchra（part．），Pellegr．Mém．Soc．Zool．France，xvi．1003， p． 176 （1904）．
Depth of body $21-2{ }_{3}^{1}$ in the length，length of head $2 \frac{4}{5}-3$ ． Snout shorter than postorbital part of head．Diameter of cye $2 \frac{1}{2}$ in the length of head，interorbital width $2 \frac{1}{2}-2 \frac{2}{3}$ ． Depth of preorbital equal to diameter of eye or less． Maxillary extending to the vertical from anterior margin of eye；jaws equal anteriorly；fold of the lower lip not con－ tinuous or subcontinuous；cheek with 3 series of scales； preoperculum scaleless； 5 or 6 gill－rakers on the lower part of
anterior arch. Scales $26-.28{ }_{8-9}^{3}, 1$ or $1 \frac{1}{2}$ between lateral line and anterior rays of soft dorsal. Dorsal * XIV-XV 10-11, commencing above opercular cleft, the spines increasing in length to the last, which is nearly $\frac{1}{2}$ the length of head; fourth spine nearly $\frac{1}{3}$ the length of head; soft fin pointed, the longest rays extending to the middle of caudal. Anal III 8-9. Dorsal and anal fins scaleless. Pectoral nearly as long as the head; ventral extending to or a little beyond origin of anal; caudal subtruncate or rounded. Caudal peduncle $\frac{3}{5}-\frac{4}{5}$ as long as decp. Olivaccons, with 5 dark cross-bars, the third bearing a blackish blotch below the lateral line; sides of head and anterior part of body with blue spots; 2 or 3 oblique blue lines from cye to maxillary ; fins dusky, the posterior part of the soft dorsal with oblique series of spots, the caudal obscurely spotted.

Panama; North-western Ecuador.

## 7. Acara equinoctialis, sp. n.

Chromis rivulata (part.), Günth. Proc. Zool. Soc. 1859, p. 418.
Acara pulcha (part.), Günth. Cat. Fish. iv. p. 280 (1862).
Acara rimulata (part.), Bouleng. Boll. Mus. Torin. xiv. 1899, no. 335, p. 5; Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 177 (1904).

Depth of body $2-2 \frac{1}{5}$ in the length, length of head $2 \frac{2}{3}-2 \frac{4}{5}$. Snout shorter than postorbital part of head. Diameter of eye $2 \frac{4}{5}-3 \frac{3}{5}$ in the length of head, interorbital width $2 \frac{1}{2}-3$. Depth of præorbital equal to the diameter of cye or less. Maxillary extending to the vertical from anterior margin of eye; jaws equal antcriorly ; fold of the lower lip not continuous; cheek with 3 series of scales; preoperculum scaleless ; 8 or 9 gill-rakers on the lower part of anterior arch. Scales $25-26 \frac{3-3^{2}}{8-9}, 1 \frac{1}{2}$ between lateral line and anterior rays of soft dorsal. Dorsal XIII-XV 10-12, commencing above the opercular cleft, the spines subequal from the fifth, which is more than $\frac{2}{5}$ the length of head; soft fin pointed, extending nearly to middle of caudal. Anal III 8-9. Dorsal and anal fins scaleless. Pectoral at least as long as the head; ventral extending to origin of anal or beyoud. Caudal subtruncate or rounded. Caudal peduncle $\frac{3}{5}-\frac{3}{4}$ as $l_{\text {long as deep. }}$ Olivaceous, with darker cross-bars, the first crossing the first 7 or 8 scales of the lateral line, the second the 9 th or loth and 3 succeeding scales of the lateral line, bearing a large

[^41]blackish blotch below the lateral line; sometimes a dark vertical stripe below the eye; 2 or 3 blue lines from eye to maxillary ; sides of head and anterior part of body with blue spots; vertical fins dusky, obscurely spotted.

Western Ecuador.
1-4. ( $52-96 \mathrm{~mm}$.) types of the species. W. Ecuador.
$5-6$. ( 55 and 76 mm .) Rio Vinces.
Dr. H. Festa.
Although similar to $A$. rivulata in colour, this species is markedly different in other characters.

## 8. Acara rivulata.

Chromis rivulata (part.), Giunth. Proc. Zool. Soc. 1859, p. 418.
Acara pulchra (part.), Günth. Cat. Fish. iv. p. 280 (1862).
Acara rivulata (part.), Bouleng. Boll. Mus. Torin. xiv. 1899, no. 335, p. 5 ; Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 177 (1904).

Depth of body $2 \frac{1}{5}-2 \frac{2}{5}$ in the length, length of head 3. Snout as long as postorbital part of head. Diameter of eye $3 \frac{2}{2}-4$ in the length of head, interorbital width $3-3 \frac{1}{4}$. Depth of preorbital $1-1 \frac{1}{4}$ the diameter of eyc. Maxillary not extending to the vertical from anterior margin of eye ; jaws equal anteriorly; fuld of the lower lip not continuous; cheek with 3 or 4 series of scales; preoperculum scaleless; 7 or 8 gill-rakers on the lower part of anterior arch. Scales $27-28 \frac{3-4}{9-10}, 1 \frac{1}{2}$ between lateral line and anterior rays of soft dorsal. Dorsal XIV-XV 10-12, commencing above the opercular cleft, the spines increasing in length to the last, which is a little more than $\frac{2}{5}$ the length of head; fourth spine $\frac{1}{3}$ the length of head or a little less; soft fin pointed, the longest rays extending nearly to middle of caudal, sometimes beyond. Anal III 8-9. Dorsal and anal fins sealcless. Pectoral nearly as long as the head; ventral extending nearly to origin of anal ; caudal rounded; caudal peduncle as long or nearly as long as deep. Brownish above, yellowish below; 4 or 5 cross-bands on the side which are much broader than the interspaces between them, the first crossing the first 7 or 8 scales of the lateral line, the second the 9 th or 10 th and 3 succeeding scales of the lateral line, bearing a large blackish blotch below the lateral line; a blackish vertical stripe below the eye; 3 blue lines from ere to max¡illary; sides of head with blue spots; vertical fins dusky, obscurely spotted.

Western Ecuador.

[^42]
## 9. Acara Geayi.

? Acara Heckelii, Müll. \& 'Trosch. in Schomburgk, Guiana, iii. p. 624 (1848) ; Günth. Cat. Fish. iv. p. 279 (1862).

Acara Geayi, Pellegr. Bull. Mus. Paris, 1902, p. 417 ; Mém. Soc. Zool. France, xvi. 1903, p. 178 (1904).
Depth of body 2-21 in the length, length of head 3. Snout longer than postorbital part of head. Diameter of eye $245-3$ in the length of head and equal to the interorbital width. Depth of preorbital greater than diameter of eye. Maxillary not reaching the vertical from the anterior margin of eye ; jaws equal anteriorly ; fold of the lower lip not continuous; cheek with 4 or $\overline{5}$ series of scales, preoperculum scaleless; 7 gill-rakers on the lower part of anterior arch. Scales 26-2 $\underset{\frac{4}{9}}{4}$. Dorsal XIV-XV 9-11, commencing a little in advance of the opercular cleft, the spines subequal from the fourth, the last $\frac{1}{2}-\frac{3}{5}$ the length of head. Anal III 8. Dorsal and anal fins scaleless. Pectoral as long as the head; ventral extending to middle of anal; caudal truncate. Caudal peduncle $\frac{5}{6}$ as long as deep. Brownish; a curved blackish band from the origin of dorsal through the eye to the suboperculum and another from below the middle of the spinous dorsal across the side nearly to the mid-ventral line. Soft dorsal, anal, and caudal with light spots.

Guiana.

1. $(84 \mathrm{~mm}$.)
2. ( 91 mm .)

Essequibo. Cayenne.

Mr. Ehrhardt.
Warsaw Museum.

## 10. Acara zamorensis, sp. n.

Acara syspilus (non Cope), Bouleng. Boll. Mus. Torin. xiv. 1899, no. 335, p. 6.
Acara vittuta (part.), Pellegr. Mém. Soc. Zool. France, xri. 1903, p. 173 (1904).

Depth of body $2 \frac{\%}{\overline{3}}$ in the length, length of head 3. Snout shorter than the postorbital part of head. Diameter of eye $3 \frac{1}{2}$ in the length of head, interorbital width 3. Depth of preorbital equal to diameter of eye. Maxillary extending to the vertical from anterior margin of eye; jaws equal anteriorly; fold of the lower lip not continuous; cheek with 3 series of scales; preoperculum scaleless; 5 gill-rakers on the lower part of anterior arch. Scales $27 \frac{3}{8}$, 1 between lateral line and anterior rays of soft dorsal. Dorsal XIII (XIV 9) 10, commencing behind the opercular cleft, the spines increasing in length to the last, which is $\frac{2}{5}$ the length of head; fourth spine $\underset{f}{?}$ the length of head; longest
soft rays extending to anterior $\frac{1}{4}$ of candal. Anal III (7-8) 9 . Dorsal and anal tins scalcless. Pectoral the length of head; ventral extending to origin of anal; candal subtruncate. Caudal perduncle $1 \frac{1}{5}$ as long a deep. Reddish brown, with about 7 blackish cross-bars, the first three bearing longitudinally expanded blotehes below the lateral line; a faint dark bar below the posterior part of eye; a dark spot at the base of caudal; sides of head and anterior part of body with blue spots; vertical fins dusky, posterior part of dorsal and the caudal obscurely spotted.

Amazons of Ecnador.

1. (101 mm.) type of the species. Liio Zamora. Dr. H. Festa.

## 11. Acara sapayensis.

Acara sapayensis, Tegan, Aun. \& Mag. Nat. Hist. (7) xii. 1903, p. 628. Acerariculuta (part.), Pellegr. Mém. Suc. Zool. France, xvi. 1903, p. 177 (1904).

Depth of body 23 in the length, length of head 25.5 . Snout a little shorter than postorhital part of head. Diameter of ere $3 \frac{1}{4}$ in the length of head, interorbital width $2 \frac{3}{3}$. Depth of preorbital $\frac{3}{4}$ the diameter of eye. Maxillary extending to the vertical from the anterior margiu of eye; lower jaw a little shorter than the upper; cheek with 3 series of scales ; preoperculum scaleless ; 5 gill-rakers on the lower part of anterior arch. Scales $26 \frac{3}{8}$, 1 between lateral line and anterior rays of soft dorsal. Dorsal XV 10, originating behind the opercular cleft, the spines increasing in length to the last, which is $\frac{3}{7}$ the length of head ; fouth spine $\frac{1}{4}$ the length of head; soft fin pointed, the longest rays extending beyond the middle of caudal. Anal III 8. Dorsal and anal fins scaleless. Pectoral nearly as long as the head ; ventral extending to origin of anal ; caudal subtruncate. Caudal peduncle $\frac{ \pm}{5}$ as long as decp. Brown, with 6 or 7 blackish cross-bars on the upper half of the body, extending on to the base of the dorsal fin ; some oblique line lines from eye to maxillary and blue spots on the side of the head; vertical fins dusky.
N.W. Ecuador.

1. ( 114 mm .) type of the species. R. Sapayo. Mr. Rosenberg.

## 12. Acara guiamensis, sp. n.

Depth of body 2 in the length, length of head 3. Snout shorter than postorbital part of head. Diameter of eye $3 \frac{1}{4}$
in the length of head,'interorbital width $2 \underset{\text {. }}{3}$. Depth of preorbital $\frac{3}{4}$ the diameter of eye. Maxillary extending to the rertical from anterior margin of eye ; jaws equal anteriorly; fold of the lower lip continuous; cheek with 3 series of scales; preoperculum scaleless; 5 gill-rakers on the lower part of anterior arch. Scales $255_{8}^{3 .}$ Dorsal XIII 10, commencing above the opercular cleft, the spines subequal from the fourth, the last nearly $\frac{1}{2}$ the length of head, the middle soft rays elongate, extending to the end of caudal. Anal III 7. Soft dorsal and anal scaly at the base. Pectoral longer than the head; rentral extending a little beyond the origin of anal; caudal rounded. Caudal pectuncle $\frac{5}{8}$ as long as deep. Body with 5 or 6 dark cross-bars, the second crossing the 7 th to 10 th scales of the lateral line and bearing a large darker blotch below the lateral line; the third and fourth bars with smaller and fainter blotches ; a dark bar below the posterior part of eve and a dark spot on the upper half of the bise of caudal ; soft dorsal, posterior part of anal, and base of caudal spotted.

Guiana.

1. ( 110 mm. ) type of the speries. Guiana. Berlin Mus umm.

## 13. Acara portalegrensis.

? Acura dimerus, Heck. Ann. Mus. Wien, ii. 1840, p. 341; Günth. Cat. Fish. iv. p. 277 (1862).
Acara portalegrensis, Hensel, Arch. f. Nat. 1870, p. 52 ; Pellegr. Mém. Soc. Zool. France, xri. 1903, p. 173 (1904).
Depth of body 2 in the length, length of head $2^{2}-3$. Snout shorter than postorbital part of head. Diameter of eye $2 \frac{1}{2}-3 \frac{1}{2}$ in the length of head, interorbital width $2 \frac{1}{4}-2 \frac{1}{2}$. Depth of prieorbital $\frac{1}{3}-\frac{3}{4}$ the diameter of eye. Maxillary extending to or bevond the vertical from anterior margin of eve; jaws equal anteriorly ; fold of the lower lip not continuous; cheek with $2-3$ series of scales; preoperculum scaleless; 5 or 6 gill-rakers on the lower part of anterior arch. Scales 24-26 $\frac{3}{8-9}$. Dorsal XIV-XVI 9-11, commencing above the opercular cleft, the spines not or but slightly increasing in length posteriorly, the last $\frac{2}{5}-\frac{1}{2}$ the length of head, the longest rays extending to middele of caudal or beyond. Anal III 8-10. Soft dorsal and anal scaly at the base. Pectoral as long as the head ; ventral extending to origin of anal or beyond; caudal rounded. (andal perluncle ${ }_{3}^{\frac{1}{3}}-\frac{2}{5}$ as long as decp. Body with 8 or 9 datk cus-bands, the third bearing a blackish bloteh below
the lateral line; a dark band from eye to lateral blotch ; a dark bar or spot below the eye; a white line from eye to nostril and beyond; often a large dark ocellus on the upper part of base of caudal, this rarying considerably and sometimes completely wanting ; posterior part of soft dorsal and anal with oblique dark stripes; dark stripes on the caudal more or less oblique if an ocellus be present, vertical if it be absent.

## 14. Acara dorsigera.

Acara dorsigera, Heck. Ann. Mus. Wien, ii. 1840, p. 348 ; Giinth. Cat. Fish. iv. p. 280 (1862) ; Steind. Sitzb. Ak. Wien, lxxi. 1875, p. 76; Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 174 (1904).
Depth of body 21 in the length, length of head $23-24$. IIead very similar to that of $A$. tetramerus, but with 2 series of scales on the cheek and 1 scrics on the preoperculum; 6 gill-rakers on the lower part of anterior arch. Scales 23-24 $\frac{23}{9}$. . Dorsal XIII-XIV 7-10. Anal III 8. Dorsal and anal fins scalcless. Pectoral as long as the head. Caudal rounded. Caudal peduncle $\frac{1}{2}$ as long as deep. Olivaccous, with 7 or 8 more or less distinct darker crossbars; a dark blotch below the uinth to eleventh scales of the lateral line; a dark longitudinal band from eye to lateral blotch; a dark spot on the spinous dorsal between the eighth and tenth spines; soft dorsal, anal, and caudal with series of alternate light and dark spots.
R. Amazon; R. Paraguay.

The examples described by Heckel and Steindachner measure up to 53 mm . in total length.

## 15. Acara Thayeri.

Acara Thayeri, Steind. Sitzb. Ak. Wien, lxxi. 1875, p. 68, pl. i. fig. 2 ; Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 175 (1904).
Depth of body 2 in the length, length of head 3. Snout shorter than postorbital part of head. Diameter of cye 3 in the length of head, interorbital width $2 \frac{2}{3}-2 \frac{3}{4}$. Maxillary not extending to below the eye; jaws equal anteriorly; cheek
with 2 series of scales, præoperculum with 1 series ; 6 gillrakers on the lower part of anterior arch. Scales $23-24 \frac{2}{2-9}$. Dorsal XIV-XV 9-10, commencing above the opercular cleft, the spines only slightly increasing after the fifth, the last nearly $\frac{1}{2}$ the length of head; soft fin extending to middle of caudal or beyoud. Aual III 7. Soft dorsal and anal scaly at the base. Pectoral as long as the head; ventral extending to origin of anal or beyond. Caudal rounded. Caudal peduncle $\frac{1}{2}$ as long as deep. Olivaccous, with obscure darker cross-bars ; a dark longitudinal band from eye to below the fourth scale of the lateral line; a dark blotch on and below the sixth to the tenth scales of the lateral line, and another above it extending on to the spinous dorsal ; soft dorsal, anal, and caudal sometimes with dark spots.
R. Amazon.

The examples described by Steindachner measure up to 110 mm . in total length.

## 16. Acara flavilabris.

Acara flavilabris, Cope, Proc. Am. Phil. Soc. xi. 1870, p. 572, and xvii. 1878, p. 696 ; Proc. Ac. Philad. 1872, p. 255, pl. xi. fig. 4.

Closely allied to $A$. Thayeri, which it resembles in having 2 series of scales on the cheek and 1 series on the preoperculum, and quite wrongly placed in the synonymy of A. tetramerus by Steindachner and by Pellegrin. Dorsal X VI 9-10. Anal 1II 7. Scales $24 \frac{22_{2}}{8}$. Caudal peduncle apparently more than $\frac{1}{2}$ as long as deep. A dark blotch on the lateral line before the middle of the side of the body ; a dark bar at the base of caudal; lower lip yellowish.

River Ambyiacu, Upper Amazon.
Cope states that all five specimens examined by him agree in having 16 dorsal spines.

## 17. Acara frenifera.

Acara freniferus, Cope, Proc. Ac. Philad. 18i2, p. 255 ; Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 177 (1904).
Apparently allied to the preceding species, but with more numerous scales, 28-29 in a longitudinal series. Dorsal XVI 10-11. Anal 1II 8. Body with dark cross-bars; a blackish spot below the middle of the dorsal fin, comected with the cye by a blackish longitudinal band.

River Ambyiacu, Upper Amazon.

## 18. Acara Maronii.

Acara Maronii, Steind. Denkschr. Ak. Wien, xliii. 1882, p. 141, pl. ii. fig. 4 ; P'ellegr. Mém. Soc. Zool. France, xvi. 1903, p. 179 (1904).
Depth of body $1_{3}^{2}-1 \frac{3}{3}$ in the length, length of head 3. Snout considerably shorter than postorbital part of head. Diameter of eye 3 in the length of head, interorbital width $2 \frac{1}{2}$. Depth of preorbital $\frac{3}{4}$ the diameter of eye. Maxillary extending to the vertical from anterior margin of eye; jaws equal anteriorly ; fold of the lower lip slightly interrupted; cheek with 3 series of scales, preoperculum with 1 or 2 series; 5 or 6 gill-rakers on the lower part of anterior arch. Scales $24 \frac{3,4}{9}$. Dorsal XV 10-11, commencing above the opercular eleft, the spines not or but slightly increasing in length posteriorly, the last $\frac{1}{2}$ the length of head, the longest soft rays produced to or beyond the end of caudal. Anal III 9-11. Soft dorsal and anal strongly scaly at the base. Pectoral as long as the head; ventral extending beyond origin of anal, sometimes nearly to the posterior end of base of anal ; caudal romded. Caudal peduncle $\frac{1}{4}-\frac{1}{3}$ as long as deep. Brownish ; a blackish curved band from origin of dorsal throngh ere to suboperculum; a blackish blotch above the lateral line below the posterior dorsal spines.

Guiana.

|  | 2. (83 and 87 mm .) | Surinam. | Mr. Kappler. |
| :---: | :---: | :---: | :---: |
|  | 3. ( 77 mm .) | Demerara. | F. G. Beckford, |

Nannacara, gen. nov.
Closely allied to Acara, but the upper lateral line runs obliquely upwards to the spinous dorsal, from which it is separated by only half a scries of scales for most of its length.

A single species from the Essequibo.

## Nannacara anomala, sp. n.

Acara punctulata (part.), Güuth. Ann. \& Mag. Nat. Hist. xii. 1863, p. 441.

Depth of body $2 \frac{3}{4}$ in the length, length of head 3 . Snout much shorter than postorbital part of head. Diameter of eye 3 in the length of head and greater than the interorbital width. Depth of preorbital $\frac{1}{3}$ the diameter of eye. Maxillary extending to below the eye ; jaws equal auteriorly ; fold of the lower lip continuous; cheek with 2 series of seales, preopercuhum with 1 series; 5 or 6 gill-rakers on the
lower part of anterior arch. Scales 23-24 $\frac{13-2}{8}$, $\frac{1}{2}$ a scale between upper lateral line and dorsal fin for most of its length. Dorsal XVI 8, commencing above the opercular cleft, the spines subequal or slightly increasing after the sixth, the last nearly $\frac{1}{2}$ the length of head; soft fin extending beyond middle of caudal. Anal III 8. Pectoral as loug as the head; rentral extending to origin of anal. Caudal rounded or pointed, the middle rays being somewhat produced. Caudal peduncle $\frac{1}{2}$ as long as decp. Brownish, with a dark longitudinal stripe from eye to base of candal and a dark oblique stripe from eye to angle of preoperculum ; soft dorsal, anal, and caudal obscurely spotted.
R. Essequibo.

1-2. (55 and 57 mm .) types of the species. R. Essequibo. Mr. Ehrhardt.
This curious species was considered by Pellegrin to be probably identical with Biotodoma Ayussizii, Stdr. However, there is no trace of a lobe on the upper part of the anterior branchial arch, and the scaly preoperculum also separates it from the known species of Biotodoma.

## Acaropsis.

Acara (part.), Heck, Ann. Mus. Wien, ii. 1840, p. 238 ; Giunth. Cat. Fish. iv. p. 276 (1862).
Acaropsis, Steind. Sitzb. Alv. Wien, lxxi. 1875, p. 80 ; Eigenm. \& Bray, Ann. Ac. N. York, vii. 1894, p. 613 ; Pellegr. Mém. Soc. Lool. France, xvi. 1G03, p. 180 (190t).
Differs from Acara only in the somewhat larger mouth, very protractile premaxillaries, and exposed maxillary.

A single species from the Amazon, Venezuela, and Guiana.
The skeleton is very similar to that of Acara tetramerus, but the greater length of the ascending processes of the premaxillaries, which extend to above the middle of the orbit, is correlated with a somewhat shorter occipital crest and shorter and weaker parietal crests. There are $2 \bar{j}$ vertebræ $(12+13)$, the third bearing a pair of teeble inferior apophyses.

## Acaropsis nassa.

Acara nassa, Heck. Ann. Mus. Wien, ii. 1840, p. 353; Günth. Cat. Fish. iv. p. 281 (1862).
Acara cognatus, Heck. t. c. p. 356.
Acara unicolor, Heck. t. c. p. 357.
Acara (Acu'opsis) nassa, Steind. Sitzb. Al. Wien, Lxxi. 1875, p. 81, pl. ii.
Accropsis nassa, Eigenm. \& Bray, Ann. Ac. N. York, vii. 189.1, p. 613 ; Pellegr. Mém. Soc. Zool. France, xvi. 100:', p. 180 (1904).
Ann. de Jag. N. Hist. Ser. 7. Vol. xv.

Depth of body $2-2 \frac{1}{4}$ in the length, length of head $2 \frac{3}{5}-2 \frac{3}{4}$. Snout not longer than eye, the diameter of which is $2 \frac{2}{3}-3 \frac{1}{3}$ in the length of head and equal to or greater than the interorbital width. Depth of preorbital $\frac{1}{4}$ to a little more than $\frac{1}{3}$ the diameter of eye. Mouth oblique; lower jaw projecting ; maxillary extending to below anterior part or middle of eye; promaxillary processes extending to above posterior margin of eye; cheek with 2 or 3 series of scales, none on the preoperculum; 10-11 gill-rakers on the lower part of anterior arch. Scales $23-24 \frac{3}{5-9}, \frac{1}{2}$ a scale between lateral line and anterior rays of soft dorsal. Dorsal XIII-XIV 9-11, commencing above the opercular cleft, the spines increasing in length to the last, which is $\frac{1}{2}$ the length of head, the soft fin pointed, extending to middle or posterior extremity of caudal. Anal III 8-9. Dorsal and anal fins scalcless. Pectoral longer than the head, extending to above middle of anal. Caudal rounded. Caudal peduncle $\frac{1-\frac{3}{3}}{}$ as long as deep. Brownish ; a blackish spot on the middle of the side, another at the origin of the lateral line, a third below the posterior part of eye, and a fourth on the angle of the præoperculum, the last often ocellated ; a dark spot on the upper $\frac{1}{2}$ of the base of caudal; soft vertical fins usually with small dark spots.
R. Amazon ; R. Orinoco ; Guiana.

## Astronotus.

Astronotus, Swains. Nat. Hist. Fish. ii. p. 229 (1839) ; Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 182 (1904).
Acara (part.), Heck. Ann. Mus. Wien, ii. 1840, p. 338.
Hygrogonus, Guinth. Cat. Fish. iv. p. 303 (1862).
Astronotus (part.), Eigenm. \& Bray, Ann. Ac. N. York, vii. 1894, p. 615.

Body ovate, compressed; scales rather large, ctenoid. Two lateral lines. Mouth moderate ; maxillary scarcely exposed ; jaws with small conical teeth in bands and with an outer series of rather strong teeth; upper surface of head scaly to between the orbits; cheeks and opercular bones scaly ; præoperculum entire. Gill-rakers few and short. A single dorsal, with XII-XIV 19-21 rays; anal with III $15-16$ rays; soft vertical fins densely covered with small
scales; caudal rounded. Pectoral asymmetrical, with 15 rays; ventrals a little behind the base of the pectoral.

A single species from South A merica.
The skeleton is very similar to that of Acara tetramerus, but there are 31 vertebre $(16+15)$, the third and fourth forming a very distinct inferior process for the attachment of the pharyngeal muscles.

## Astronotus ocellatus.

Lobotes ocellatus, Agass. in Spix, Pisc. Bras. p. 129, pl. 1xviii. (1829).
Astromotus ocellatus, Swains. Nat. Hist. Fish. ii. p. 229 (1839); Eigenm. \& Bray, Amn. Ac. N. York, vii. 1894, p. 617 ; Pellegr. Mém. Soc. Zool. France, xvi. 1903, p. 182 (1904).
Acara crassispinis, Heck. Ann. Mus. Wien, ii. 1840, p. 350.
C'ychla rubroocellata, Schomb. Fish. Guiana, ii. p. 153, pl. x. (1843).
Hygrogonus ocellatus, Günth. Cat. Fish. ir. p. 303 (1862).
Acura compressus, Cope, Proc. Ac. Philad. 1872, p. 256.
Acara ocellata, Steind. Sitzb. Ak. Wien, lxxi. 1875, p. 77.
Acara hyposticta, Cope, Proc. Am. Phil. Soc. xrii. 1878, p. 697. Astronotus ocellatus, var. zebra, Pellegr. t. c. p. 183. Astronotus hypostictus, Pellegr. l. c.
Depth of body $2-2 \frac{1}{4}$ in the length, length of head 3. Snout as long as or longer than eye, the diameter of which is $4-4 \frac{1}{3}$ in the length of head, interorbital width $2 \frac{1}{4}-2 \frac{1}{3}$. Depth of præorbital $\frac{1}{2}$ the diameter of eye. Mouth oblique; lower jaw slightly projecting; maxillary very slightly exposed, extendingo to below anterior $\frac{1}{2}$ of eye ; præmaxillary process extending to above anterior $\frac{1}{4}$ of eye ; cheek with 7-9 series of scales, none on the præoperculum ; 7-9 gill-rakers on the lower part of anterior arch. Scales 33-38 $8_{17}^{6 \frac{6}{2}-\frac{1}{2}-20}$, those of the thoracic region considerably smaller than on the sides of the body. Dorsal XII-XIII (XIV) 19-21, commencing above the opercular cleft, the spines slightly increasing in length to the last, which is $\frac{1}{3}$ the length of head. Anal III 15-16. Pectoral nearly as long as the head. Caudal rounded. Caudal peduncle $\frac{-1}{5}-\frac{1}{2}$ as long as deep. Brownish, with a blackish ocellated spot on the upper $\frac{1}{2}$ of the base of caudal and sometimes 2 or 3 more on the base of the soft dorsal ; pectoral with a blackish spot on the inner side near the base.

Guiana; R. Amazon; R. Paraguay.

1. (255 mm.) Teffé. Mr. Salmin.

Dr. A. Borelli. Paris Museum.
XLIII.-Notes on the Natural History of East Finmark. By Canon A. M. Norman, M.A., D.C.L., LL.D., F.R.S., F.L.S.
[Concluded from vol. xii. p. 417.]
The delay which has taken place in the conclusion of these motes has arisen from two or three minute Colenterata which I was unable to identify and which required a good deal of working out. Pressure of other work has prevented this being done, and as the other species of Colenterata were neither numerous nor for the most part rare, I have now thought it best to omit the Cœelenterata altogether, and to no longer delay the printing of the notes on Foraminifera and on Botany which have been so long awaiting publication.

## FORAMINIFERA.

Astrorliza limicola, Sandahl.
Psammosphera fusca, E. Schulze.
Hyperammina subnodosa, H. Brad5.
Rhabdammina discreta, H. Brady.
Haplophragmium latidorsatum, Borneman.
-globigeriniforme, Parker \& Jones.

- glomeratum, H. Brady.
——canariense, d'Orbiguy.
_-crassimaryo, Norman, nom. nov. Brady, 'Challenger' Foram. p. 310, pl. xxxy. fig. 4 ; Goës, "Synopsis Arctic and Scandinavian Recent Marine Foraminifera" (Kongl. Svenska Vet.Akad. Handl. vol. xxr. 1894, p. 21, pl. v. figs. 92-94). A larger and much more tumid form than canariense, and the two are quite distinct when found living in company.
Reoplax fusiformis, Williamson.
Hippocrepina indivisa, Parker.
Trochammina squamata, Parker \& Jones.
Ammodiscus incertus, d'Orbigny.
- charoides, Jones \& Parker.

Webbina hemispherica, Jones, Parker, \& Brady.
Spiroplecta biformis, Parker \& Jones.
Valvuíina conica, Parker \& Jones.
Cassidulina levigata, d'Orbigny.

- crassa, d'Orbigny.

Butimina pyrula, d'Orbigny.

- arctica, d'Orbigny.
- elegans, d'Orbigny.
- fusiformis, Williamson.

Virgutina Schreibersiana, Czjzek.
Bolivina punctata, d'Orbigny.
—_plicata (d’Orb.), Brady.
Uvigerina angutosa, Williamson.

- tenuistriata, Reuss.

Polymorphina problema, d'Orbigny.

- rotunduta, Borneman.
——compressa, d'Orbigny.
—amygdaloides (Reuss), Brady.
- gibba, d'Orbigny.

Cristallaria crepidula, Fichtel \& Moll.
Nodosaria soluta, Reuss.

- lavigata, d'Orbigny.
——acuminata, Reuss ( $=$ Psecadium acuminatum, Reuss). A produced form of $N$. levigata with oblique suture (see Schlicht, 'Foram. des Septentrienthones ron Pictzpuhl,' 1870, pl. xxv. figs. 1-10).
——communis, var. Verneuillii, d'Orbigny.
- calomorphu, Reuss.
- pauperata, d'Orbigny. The specimens thus named are from the Varanger and Bög Fiords. Dr. H. B. Brady examined them and called them "radicula running into N. brevis," but they exactly correspond to the Greenland form assigned by Goës to N. pauperate as "megulosphericce," and figured by him (l. c. pl. xii. figs. 677-683).
Lagena globosa, Walker \& Jacob.
- lavis, Montagu.
-- striata, d'Orbigny.
- distoma, Parker \& Jones.
- lineata, Williamson.
- semilineata, J. Wright.
- costata, Williamson.
-     - , forma acuticosta, Reuss.
- finmarchica, sp. n. This is a very beautiful Lagena belonging to the striato-punctata group, haring a form not unlike that species and with the same rery slender neck. It is latger than any specimen of striato-punctata that I have seen. Its marked character consists in the costæ, which are each composed of three very distinct riblets, while the puncta, instead of being
on the costre, are between them, as in L. Fieldingiana. A single specimen mas taken at Vadsö, near the entrance to the harbour, in 10-25 fathoms.
Lagena squamosa, Montagu.
- hexagona, Williamson.
- levigata, Reuss.
- lagenoides, Williamson.
- Orbigniana, Sequenza.
- pulchella, H. B. Brady.

Globigerina bulloides, d'Orbigny.
Pullenia spharoides, d'Orbigny.
Truncatulina Tobatula, Walker \& Jacob.
Patellina corrugata, Williamson.
Pulvinulina Lírsteni, Reuss.

- exigua, H. B. Brady.

Polystomella striato-punctata, Fichtel \& Moll.
Nonionima umbilicata, Montagu.

- depressula, Walker \& Jacob.
- stelliyerc, d'Orbigny.
——scapha, Fichtel \& Moll.
——turgida, Williams. communis, d'Orbigny. This approaches very closely to $N$. turgida in general characters, but instead of being very tumid, as in that species, it is as compressed as N. scapha. Dr. H. B. Brady saw my specimens, and referred them to N. communis, d'Orbigny (For. Foss. Vien. p. 108, pl. v. figs.7, 8). It was taken on the same ground as $N$. turgida, and was distinguishable at a glance; nor could I find any intermediate forms.
Operculina ammonoides, Gronovius.
Miliolina tricarinata, d'Orbigny.
- trigonula, Lamarek.
- seminulum, Linné.
- subrotunda, Walker \& Boys.

Biloculina ringens, Lamarck.

## BOTANY.

Dredging or shore-collecting every day, and on arriving at home the sorting and preserving of the captures, left little time for botanizing. Still some was made. In the middle of the day we always landed at some new spot, and after a hurried luncheon Schneider and myself set off to explore
the neighbouring ground while the boatmen were finishing their dimner, resting, and smoking. Thus three quarters of an hour was spent by him in entomologizing, by myself in botanizing. Then at night, again, between 9 and 12 p.m. he was often busy with his net while I was plant-hunting. On Sundays a longer ramble was taken, during which many good plants were found. Still no ground was examined which was further than a mile from the shores; but had excursions been made inland among the copses and on the hills, the list of plants here given would have no doubt been considerably extended. It was a great treat to explore an Arctic flora so different in many respects from our own, represented by so many of our Alpine forms and yet including so many other beautiful species. The rarest plant I found was Arenaria lateriflora, of which I believe the only European habitat is near the falls of the Pasvic River, and as Herr Schneider was aware of this fact we did not lose the opportunity of seeking it. Dianthus superbus is a lovely pink, which was in full flower, ornamenting the cliffs on the eastern side of one of the fiords on the north coast which we passed in the steamer; but I have forgotten which fiord it was. Among the other more beautiful plants new to me were the various species of the families Polemoniacer and Ericacer. Striking among the latter were the bushes of the Arctic Ledum palustre, the delicious scent of which perfumed the air for a considerable distance from the bog in which the plants were growing.

In this high latitude, of course, large numbers of those found in the temperate climate of our islands are absent ; for instance, it may interest some reader who knows nothing of the geographical distribution of plants to mention a few of the familiar friends which he must not expect to meet with so far north. There are no such shrubs as holly, ivy, honeysuckle, dog-rose (of any British species), blackberry (Rubus fruticosus), gorse, or broom. There is no common daisy ${ }^{*}$, celandine (Ranunculus ficaria), sweet violet, primrose, cowslip, bluebell $\dagger$, wood-anemone, or foxglove; the only clovers are Trifolium repens and pratensis; the only Campanula is C. rotundifolia; there are no English poppies; while Geranium pratense and the whole of the annual species of that genus are absent.

Of garden weeds the common groundsel would seem to be scarce, for I failed to find it in weedy gardens which I examined, and no other species of Senecio occurs.

[^43]There are no bindweeds (Convolvulus), no sow-thistles (Sonchus), no anmual species of Veronica, and the only Chenoporlium is C. album; and the common thistles of our fichds-Carduus mutans, acanthoides, lanceolatus, and arvensis -are not to be found.

The rapidity of growth which takes place in Arctic regions cannot fail to strike the stranger as truly wonderful. A spot, barren and brown when first scen, will a fortnight later be vivid with green clothing and bright with flowers and waving rushes and grasses. But the healthiness and vigour of plants grown in pots within doors struck me as still more remarkable. At the furthest and darkest corners of rooms, where in England they would at once pine and dic, they flourish and flower as vigorously as they would with us when grown in a sumy south window. This is no doubt accounted for by the fact that in the comparatively dark corners they receive during the twenty to twenty-four hours of daylight as much invigorating stimulus as they would do in England when subjected to a much stronger light in our shorter days. In the long rest of the winter darkness plants no doubt also lay up a force of strength ready to burst forth at the first awakening from their sleep.

In 1860 Sir Joseph D. Hooker published, in Trans. Linn. Soc. vol. xxiii. pp. 251-348, an exhaustive paper, "Outlines of Distribution of Arctic Flants." He there estimates the total number of flowering plants found within the circumpolar Arctic circle to be 762 species. Of these he gives no less than 616 as occurring in Arctic Europe, 586 of which he regards as of Scandinavian origin, and the small remaining 30 as of American or Asiatic origin. Zoologists no longer regard the Arctic Circle as the boundary of the Arctic fauna, but take an isothermal line. Now if we take as our isothermal line that which indicates an average temperature throughout the year of the freezing-point, $32^{\circ}$ Fahr., we shall find that the whole of Western, by far the larger part of Central, and all Northern Norway except the extreme north-east, where I was working, have a higher temperature. With such a boundary a very large number of the species regarded by Hooker as Aretic would be excluded. On the other hand, if the same isothermal line be followed across America and Asia, it will be found very far south of the Aretic Circle in America, passing about $50^{\circ} \mathrm{W}$. through the most southern extremity of Hudson's Bay, and in Asia, in about the same latitude, crossing Lake Baikal. Using, then, this isothermal, it would follow that almost the whole of Norway would be excluded, while in America and Asia vast regions
would be added. An estimation of the flora of such regions would give extremely different figures from those given by Hooker relating to plants found north of the arbitrary line of the Aretic Circle irrespective of climatic conditions.

In the voyage homewards from Vadsö to the Lofoten Islands, where I stopped for a few days, I was so fortunate as to find in a fellow-passenger Herr A. Landmark, the Government Inspector of Inland Fishery in Normay, who is a very good botanist. He went through my herbarium, and kindly named for me many plants with which otherwise I should have found much difficulty, e. $g$. the species of Eriophoron. He also was so good as to give me several plants which he had collected at Tana and Nyborg, and which I have included in the following lists. In England I am much indebted to the kindness of two specialists who determined for me the difficult Salices and the Carices and allies, Dr. F. Buchanan White having examined the former and Mr. Arthur Bennett the latter.

In the following list I have indicated the exact localitics where the plants were procured by the use of initial letters, as below :-
B. Bög Fiord (on or near the shores of).
K. Klosterelv Fiord (on or near the shores of).
L. Lang Fiord (on or near the shores of).
N. Nyborg (Herr Landmark).
P. Elvenes and Pasvic River.
S. Kirkenes and its neighbourhood in Sydvaranger.
T. Tana (Herr Landmark).
V. Vadsö and Nordvaranger.

The nomenclature of species in the following list is that of C. J. Hartman's 'Handbok i Skandinaviens Flora,' but I have not adopted his arrangement of families, which is that of Fries, but have followed that which is better known to English botanists.

Ranuncllacefe.
Ranunculus lapponicus, Lin. P. $\quad$ Thalictrum kemense, Fr. T.

- hyperboreus, Rottb. V., N.
- acris, Lin. V.

Caltha palustris, Lin. V.
Trollius europæus, Lin. V.

## Cructperas.

Cardamine pratensis, Lin. Capsella bursa-pastoris, Lin. Cochlearin officinalis, Lin.

Draba incana, Lin. V., S.
——hirta, Lin. T.

Violacef.
Viola suecica, Fr. V., N.
| Viola biflora, Lin. V.
Droseracere.
Drosera rotundifolia, Lin.
| Drosera longifolia, Lin.

## Caryophyliacee.

Silene acaulis, Lin.
Melandrium sylvestre, Röhl, var. alpestre, Fr. T.
Dianthus superbus, $L i=$
Stellaria nemorum, Lin. S.

- media, Lim. S.
-uliginosa, Murr. V.
——crassifolia, Ehrb. S.

Stellaria humifusa, Roth. L.

- alpestris, Fr. L.

Cerastium alpinum, Lin.

- triviale, Link. P.

Arenaria lateriflora, Lin. P. IIelianthus peploides, Lin. S. Sagina nivalis, Lindbl. T. ——saxatilis, Wimm. S.

Geraniacee. Geranium sylvaticum, Lin. V.

Leguminose.
Lathyrus palustris, Lin. N. - maritimus, $F r$. S.

Vicia cracca, Lin. S.
Astragalus alpinus, Lim. N.
Oxytropis campestris, $D C . \mathrm{N}$. Phaca frigida, Lin. N. Trifolium repens, Lin.

Rosacee.

Prunus padus, Lin.
Spiræa ulmaria, Lin. V.
Alchemilla vulgaris, Lin. V.

- alpina, Lin. V.

Potentilla anserina, Lin. S.

## Corrigenda \&c. ('Annals,' 1903.)

Vol. xi. p. 569.-For "Berenicea prominens, Lamouroux (Expos. méthod. des Genres de l'Ord. des Polypiers, 1821, p. 80, pl. lxxx. figs. 1, 2)," read Berenicea ammulata (p.81,
pl. lxxx. fig. 6). To anyone consulting the plate it must be obvious that the reference was, by some mistake which I am unable to account for, erroneous, and that the netted state of Hincks's Chorizophora Brongniartii is fig. 6. It follows that while the specific name annulata should, in my opinion, supersede that of Brongnartii, the gencric name Chorizophora must be retained.

Vol. xi. p. 577.-For Bugulopsis Peachii read
Bugula elongata, Nordgaard.
1902. Bugula elongata, Nordgaard, "Die Bryozoen des westlichen Norwezens," Die Meeresfauna von Bergen, p. 140, pl. i. figs. 1-6.

The specimens which I referred to Bugulopsis Peachii must be transferred to the Bugula elongata of Nordgaard. The general resemblance of the two species is remarkable: in form of zoœcia and oœcia they are almost identical ; moreover the peculiar sculpturing of the latter is of similar character. The chief point of

difference consists in the occasional development in Bugula elongata of a very minute avicularium, situated on the middle of the side of the zoœcium, from which it usually hangs as it were backwards, as shown in the woodent here given; but these avicularia are rarely developed, and there may be an entire zoarium without any avicularia. The other points in which the species
may be distinguished from Buyulopsis are that the form of growth in the latter is that of a little bush and the zoarium is charged with carbonate of lime; in B. elongata the growth is from a single stem giving forth brauches for the most part dichotomously, and the zoarium is altogether chitinous, as is usual in the genus Bugula. These last differences were regarded by me as simply varictal, and it was not until my attention was directed to his species by Herr Nordgaard that I discovered on some of my specimens a few of the peculiar avicularia. It is probable, as suggested to me by Herr Nordgaard, that other records of Bugulopsis Peachii from Aretic localities may likewise be referable to his species; and I find that I have this form from as far south as the Bergen and Hardanger Fiords. In the adjoining woodcut, fig. l represents the zoocia, oœeia, and avicularium of Buyula elongata, fig. 2 the avicularium more magnified, fig. 3 radii of the oœcium highly magnified, while fig. 4 illustrates the corresponding radii in the oœcium of Bugulopsis Peachii for comparison.
Vol. xi. pp. 580 \& 581.-For Kinekoskias read Kinetoskias.
Vol. xi. p. 595.-"Genus Oochilina, gen. nov. Type Oochilina (Membranipora) crassimarginata, Hincks." Mr. Waters kindly called my attention to the fact that M. F. Canu had in 1900 instituted a subgenus Crassimarginitella, with the same type, Membranipora crassimarginata, Hincks (Canu, " Révision des Bryozoaires du Crétacê figurés par d’Orbigny," Bull. Soc. Géol. France, sér. 3, vol. xxviii. 1900, p. 369). This paper was not in my library when I wrote, and the Zool. Record, which I had consulted, contained no reference to the genus.

In this same paper of Canu the following genera may be mentioned as having reference to what I have written:-
"Rhynchotella (subgen.). Type Membranipora rhynchota, Busk," p. 367, and "Rhamphonotus, Gray (sic). Type Membranipora Flemingii, Busk," p. 417, should read Rhamphonotus, Norman. Type Rhamphonotus minax, Busk, =rhynchota.

At p. 373 a subgenus Foratella is instituted in which is placed among other species Membranipora Lacroixii, Audouin.

At p. 380 a genus Nichtina is formed with Membranipora membranacea, Linné, as its type.

At p. 382 we find Pyripora, d'Orbigny, 1847, type $P$. catenaria, Jameson. I have not seen d'Orbigny's paper of 1847, but in his ' Paléont. Française,' Terrains Crétacé, 1850-1852, p. 538, under the genus Pyripora there is no reference to the species in question, and the fossil species referred by Canu to this genus would scarcely seem to be congeneric with M. catenularia.
Vol. xii. p. 100, lines 6 \& 13.-For Membraniporella, Hincks, read Membraniporella, Smitt.
XLIV.-Description of a new Species of Opisthostoma from North Borneo. By Edgar A. Smith, I.S.O.
Altogether twenty-three species of this genus from the northern parts of Burneo have been deseribed, and probably many other forms still remain to be discovered.

Opisthostoma fraternum, sp. n.
Testa dextrorsa, pyramidalis, anguste umbilicata, rufescens; anfractus $6 \frac{1}{2}$, regulariter lente accrescentes, perconvexi, lumellis paucis, tenuibus, obliquis, in medio anfractuum in spinas productis, instructi, ultimus pone constrictus, dein descendens et subito ascendens atque retroversus, autice solutus, infra spinis excavatis cristatus; apertura subcircularis; peristoma obliquum, duplex, album, margine interno expanso, tubæformi, externo tenuissimo, aliquanto dilatato.
Diam. max. $2 \cdot 75 \mathrm{~mm}$. ; alt. $2 \cdot 25$.
The identification of many of these minute objects is almost impossible or, at all events, very uncertain, from description or figures such as have as yet appeared. It is only by actual comparison of specimens that the differences become appreciable. The present species bears a closer resemblance to O. concinnum, Fulton, than to any other. It differs from it, however, in being a trifle smaller, having more convex and higher whorls, fewer lamellæ, and the onter peristome is less interrupted on the right side. The delicate oblique lamellas are about fourteen in number upon the penultimate whorl and are produced at the middle into short hollow spines directed obliquely upwards. This row of spines is continued under the body-whorl, forming a crest, between the constriction and the peristome, of about six or seven spines. The distance of the solution of the anterior portion of the bodywhorl is a trifle variable. Even under the microscope no spiral sculpture is traceable, but some feeble lines of growth may be observed.

# XLV.—On the Skull of Gonorhynchus Greyi. By W. G. Ridewood, D.Sc., F.L.S. 

## [Plate XVI.]

Gonorhyncius, the sole existing genus of the family Gonorhynchidæ, is an aberrant Teleostean fish whose affinities have often been the subject of debate and are not even now definitely known. Having been recently engaged upon an investigation on the cranial osteology of the fishes of the families Elopidæ and Albulidæ (Proc. Zool. Soc. 190 1, ii. pp. 35-81), Mormyrida, Notopteridæ, and Iyodontide (Journ. Linn. Soc., Zool. xxix. 1904, pp. 188-217), Clupeidr (Proc. Zool. Soc., in the press), and Osteoglossidie (Journ. Limn. Soc., Zool., in the press), I took up the study of the skull of Gonorhynchus with no little interest, since there was every hope for believing that in the characters of so complex a structure evidence might be forthcoming as to the relationship existing between the Gonorhynchide and the other families of the Malacopterygii.

The material available consisted of three skulls of Gonorhynchus Greyi at the British Museum, two of them being prepared specially for the investigation. My thanks are due to Mr. G. A. Boulenger, F.R.S., for facilities offered for the examination of these specimens.

The genus Gonorhynchus was established in 1763 by Gronovius (Zooplyyl. Gronov. fasc. i. 1763, genus 199, p. 55, pl. x. fig. 2), who placed it immediately before the genus Cobitis, with which he must have thought it closely related, because in Gray's British Muscum Catalogne, printed in 1854 from the manuscript of Gronovius, the fish appears on p. 41 under the name Cobitis gonorhynchus.

Gonorhynchus was placed among the earps by Gmelin (Syst. Nat. Linn. i. 3, 1788, p. 1422), Schneider (Bloch and Schneider, Syst. Ichthyol. 1801, p. 443), Lacepède (Hist. Nat. Poiss. v. 1803, p. 570), and Cuvier (Règne Anir. ii. 1817, p. 196) ; but Valenciennes (Hist. Nat. Poiss. xix. 1846, pp. 203, 204, and 208) objected on the gromed of its numerous (nine) pyloric ceeca and because the maxille shared with the premaxillie the bounding of the upper border of the mouth. Valenciennes (l.c. p. 179) associated it with Chanos by reason of the large size of the branchiostegal membrane and the absence of teeth from the jaws. He pointed out further that Gonorhynchus, like Chanos and Albula, has a

[^44]conical hearl, with snout projecting above the reduced mouth (l. c. p. 20.4).

Gonorhynchus was obtained on the 'Erebus' and 'Terror' Expodition, and Richardson (Zool. Voy. 'Erebus' and 'Terror,' ii. Fishes, part 7, 1845, p. 44), thinking it a new genus, named it Rhynchaena, because of its projecting muzzle, and placed it among the Cyprinoids.

Schlegel (Sichold's ' Fauna Japonica,' Pisces, 1850, p. 217) placed the genus Gonorhynchus between Leuciscus and Cobitis. In Giunther's 'Catalogue of Fishes in the British Museum' (vii. 1868) the family Gonorhynchide follows the Cyprinidx and precedes the Hyodontidæ, Ostcoglossidæ, and Clupeidse; in the 'Study of Fishes,' 1880, by the same author, the family comes after the Salmonidx, Percopside, and Haplochitonidæ, and before the Hyodontidae, Pantodontide, Osteoglossidx, and Clupeidæ.

Kucr (Reise der Fregatte 'Novara,' Zool. i. 1869, Fische) placed the family Rhynchrenæ, containing the genus Gonorlynchus, between the Elopidæ, Chirocentridæ, and Lutodeirx on the one hand and the Cyprinodontes and Cyprinoidx on the other. On page 342 he notes that the form of the accessory branchial organ of Gonorhynchus testifies to the relation which this fish bears to Chanos and the true Clupeids.

By Cope ("Ichth. Lesser Antilles," Trans. Amer. Phil. Soc.n. s. xiv. 1871, p. 455) the Gonorhynchide are bracketed with the Saurida, because they have the "parictals united" and " no tail vertebre." (As is shown below, the parietals of Gonorhynchus are separated.)

Gill ("Families of Fishes," Smithsonian Miscell. Coll. 1872, p. 16) placed the family Gonorhynchidæ between the Salmonoids, Scopelids, and Alepocephalidæ on the one hand and the Hyodontidæ and Clupcide on the other.

According to Smith Woodward (Brit. Mus. Cat. Foss. Fishes, iv. 1901, p. ix) the Gonorhynchidx are but slightly modified Scopelids; but Boulenger declines to admit any close affinity between the Gonorhynchide and the Haplomi (Scopelidx, Esocidæ, \&c.), and lays stress on the presence of a mesocoracoid element in the shoulder-girdle of Gonorhynchus and its absence from that of the Haplomi. He places the family Gonorhynchide at the end of the suborder Malacopterygi, following the Salmonidæ, Alepocephalidæ, and Stomiatidx, and preceding the Cromeriide (Amm. \& Mag. Nat. Hist. (7) xiii. 1904, p. 165 ).

For a highly specialized family the Gonorhynchide are of great antiquity; they date back to the Cretaceous period,
when all the characteristic features of Gonorhynchus except the extension of scales over the head had already been acquired. The genus Notogoneus of the freshwater Eocene deposits of North America and Europe differs from the recent Gonorhynchus only in the absence of pteryg id and lingual teeth, the shape of the subopercular bone, and the position of the dorsal fin (see Smith Woodward, Proc. Zook. Soc. 1896, pp. 500-501, and B. M. Cat. Foss. Fishes, iv. p. ix).

The cranium of Gonorhynchus Greyi (Pl. XII. figs. 2, 3, and 4 ) is long and flattened, and in the ethmoid and orbital regions rather slender. The frontals form nearly the whole of the roof of the cranium and exhibit no median suture. The parictals are separated by the supraoccipital, and extend back to cover the epiotic prominences; the tubular scales of the transverse commissure of the sensory-canal system are readily removable from the parietal and supraoceipital bones, upon which they are set. The exoccipitals fail to meet above the basioccipital, so that the foramen magnum is not bounded by the exoccipitals alone. The foramen for the passage of the vagus nerve is remarkably large.

The cranium articulates with the vertebral column by a hemispherical head, which is not removable, and consists of a portion of a vertebral centrum fused with the basioccipital and lower parts of the exoccipitals. This convexity of the occipital articulation is not peculiar to Gonorhynchus, for Owen and Klein have recorded it in Fistularia (Anat. of Vert. i. 1866, p. 107, and Jahres!. Württ. 1881, p. 325), and Klein in Synynathus, Phyllopteryx, Gustrotokeus, and Ostracion (Jahresh. Württ. 1885̄, p). 108). The most recent observations are those of Starks, who states that the basioccipital condyle is a round knob in the families Fistularidæ and Aulostomidie (Proc. U.S. Nat. Mus. xxv. 1902, pp. 619-634).

The ascending wings of the parasphenoid rise high; they pass up in frout of the pro-otic and come into contact with the alisphenoid and postfirontal of each side. The parasphenoid fails to reach as far back as the posterior end of the basioccipital; the eye-muscle canal does not open posteriorly; neither the parasphenoid nor the vomer bears teeth. 'The alisphenoids are widely separated, and there is no orbitosphenoid nor basisphenoid. The ethmoidal region is long, and the mesethmoid, which is small and flat, is separated
from the prefrontals by a considerable tract of ethmoid cartilage.

The post-temporal consists almost cutirely of its epiotic limb, the only other part being a delicate sensory-canal scale of tubular shape and horizontal disposition. The anterior end of this tube is in contact with another tubular scale, which represents the supratemporal, but has not the triradiate form characteristic of the supratemporal bone in Malacopterygian fishes generally, since the forking of the horizontal sensory canal into the supraparietal commissure and the squamosal brauch occurs just in front of it, and not within it.

From the opisthotic there extends a rod of bone, a kind of intermuscular bone, in the direction of the post-temporal, which, however, it fails to reach. Fibrous tissue intervenes between its posterior extremity and the post-temporal, and the relations between the intermuscular bone and the posttemporal are such as to open up an interesting question whether the opisthotic limb of the post-temporal has not in Telcostean fishes generally the morphological value of an ossified ligament or intermuscular bonc. In view of the dermal origin of the post-temporal and the depth below the surface at which its opisthotic limb occurs it is highly probable that such is the casc. In Gonorhynchus a second and similar intermuscular bone runs from the back of the exoccipital parallel with the above, but situated nearer to the median plane and having no connexion with the posttemporal bone. Such intermuscular bones are not uncommon in Teleostean fishes, and a comparative account of them is given in the 'Proceedings of the Zoological Socicty,' 1901, ii. pp. 59, 65, 66.

The nasal is a long slender bone of tubular shape, and the preorbital (fig. 5, por) is large and has a conspicuons keel near its lower edge, as already shown by Smith Woodward (Proc. Zool. Soc. 1896, p. 503, and fig. 5, $x$ ). There are no suborbital or postorbital bones.

The gape is bounded above by the premaxillæ alone, although the maxilla is about twice as long as the premaxilla, and extends more anteriorly than that bone, as well as more posteriorly. The premaxilla articulates with the ventroexternal surface of the maxilla at about one third of the length of the latter from its anterior end; a short process of the premaxilla extends in front of this articulation, but the main part projects backward and downward. The extreme anterior end of the maxilla articulates with the cartilaginous anterior termination of the palatine. There is no articulation
between the ethmoid region of the cranium and the maxilla, nor between the ethmoid and the premaxilla. Neither maxilla nor premaxilla bears teeth; there is no surmaxilla.

The mandibular ramus ( Pl . X V I. figs. 1 and 5 ) is of remarkable shape, since the articular and dentary components of the coronoid process are widely separated, the dentary component standing high and being situated near the anterior end of the jaw. The lower margin of the gape is nearly at right angles to the long axis of the mandibular ramus. The dentary is but slightly larger than the articular and bears no teeth. The angular is distinct from the articular, and there is a sesamoid articular lying on the buccal side of the articular (fig. 1, sar).

The hyomandibular articulates with the cranium by two barely separated heads, the anterior one small and the posterior one broad. The diminution in the size of the mouth appears not to have affected the hyomandibular, the main axis of which is about vertical (figs. 1 and 5, $h \mathrm{~m}$ ) ; the symplectic, however, is sharply bent forward. The metapterygoid is reduced to a thin rod of bone which runs from the lower end of the hyomandibular to the hind end of the entopterygoid.

The entopterygoid bears at its posterior end a circular fatch of stout bluntly conical teeth, reminding one of those of Osteoglossum; but although the entopterygoid steadies itself against the side of the parasphenoid, there is no definite articulation with that bone such as occurs in Osteoglossum. The ectopterygoid is straight and does not run down the anterior edge of the quadrate. The hyopalatine arch is very thin at the junction of the palatine with the entopterygoid and ectopterygoid, and there is a ligamentous attachment here with the prefrontal. The palatine is curiously inflated and comes close to the surface of the head in front of the preorbital bone in such a manner as to simulate one of the cheek-plates. The bulk of the palatine lies in advance of the dentary symphysis (figs. 1 and $5, p l$ ).

The lower or horizontal part of the preopercular is larger than the upper or vertical part (fig. 5, pop). There are fout branchiostegal rays, the two posterior ones cousiderably larger and flatter than the other two. They are all attached to the outer face of the epihyal.

The lower hypohyal is larger than the upper. The urohyal is moderately small, and is broadened out in front into a horizontal plate. The glossohyal is narrow and tipped by a hemispherical cartilage (text-fig., $g h$ ). The first basibranchial is cartilaginous; the sccond is large and bears on
its upper surface about twenty strong blunt teeth, which engage with the teeth on the entopterygoids, and with the latter constitute the entire dentition of the animal. The third basibranchial is a small rod-like bone, clearly distinct from the second. The fourth and fifth basibranchials are

Gonorhynctus Greyi; hyobranchial skeleton, dorsal view. The epibranchials and pharygrobranchials of the right side are not shown.

represented by a rod of cartilage which is continued back for some little distance behind the mesial ends of the fifth ceratobranchials.

The last two brauchial arches are large and slender and
support the epibranchial organ. The fourth and fifth cerat()branchials are slender curved rods of bone. A fifth epibranchial (text-fig., eb 5) is present in the form of a curved rod of cartilage distinct from, but in the same line with, the posterior cartilaginous epiphysis of the fifth ceratobranchial. At its upper end it meets the Y -shaped cartilage that constitutes the posterior part of the fourth epibranchial. The ossified part of the fourth epibranchial consists of a broad thin lamina of bone, vertically disposed, and therefore seen edgewise in the text-figure.

The first hypobranchial is as long as the first ceratobranchial, the second is nearly as long as the second ceratobranchial, the third hypobranchial is cartilaginous. The first pharyngobranchial is wanting and there is no spicular bone; the second and third pharyngobranchials have the normal relations.

In utilizing the characters of the skull of Gonorhynchus as the basis for a discussion of the affinities of the genus I think it may be taken for granted that the family Gonorhyuchidæ falls within the suborder Malacopterygii as defined by Boulenger (Ann. \& Mag. Nat. Hist. (7) xiii. 1904, pp. 163-165), for the presence in the Gonorhynchidæ of a mesocoracoid element in the shoulder-girdle excludes the family from the Haplomi, and the absence of Weberian ossicles disposes of the hypothesis upheld by the earlier writers that the Gonorhynchidæ are allied to the Cyprinoids.

The extension in Gonorhynchus of the upstanding process of the parasphenoid so far as to touch the alisphenoid and postfrontal bones is paralleled in Osteoglossum, the process reaching the alisphenoid in $O$. Leichardti and the postfrontal in O. bicirrhosum and O.formosum; and the entopterygoid of Gonorhynchus bears at its posterior end a patch of stout teeth, which engage with the basibranchial teeth much as in Osteoylossum; and, further, the first basibranchial remains unossified, as in Heterotis. But the Osteoglossidie (Osteoglossum, Heterotis, and Arapaima) are a sharply delimited family, distinguished by the sculpturing of the superficial bones of the skull, the meeting of the parietal bones, the sutural union of the nasal bones with one another and with the auterior ends of the frontal bones, the presence of a stout peg-like process of the parasphenoid for articulation with the eutopterygoid, the smallness of the subopercular, the bounding of the upper border of the gape by the
maxilla as well as the premaxilla, and the absence of the lower hypohyal: none of these features are exhibited by Gonorhynchus.

The Pandodontida are more nearly allied to the Osteoglossidre than to any other family of Teleostean fishes, and resemble them in the presence of a paired peg of the parasphenoid for articulation with the entopterygoid, in the large size of the nasal bones and their incorporation into the cranium, and in the meeting of the parietal bones. In those characters in which P'antodon differs from the Osteoglosside -such, for instance, as the absence of the interopercular and the fusion of the two premaxillary bones-it does not approach the Gonorhynchidæ.

Phractolamus, the sole genus of the family Phractolamidæ, has a remarkably aberrant skull, only a few features of which can be found to recur in the skull of Gonorhunchus. Such are the failure of the first basibranchial to ossify, the small size of the mouth, the reduction of the dentition, and the formard position of the coronoid process. Of these features the first occurs in genera as remotely allied as Heterotis, Notopterus, and Cromeria, although not occurring in Osteoglossum and Arapaime, with which Heterotis has obvious relations. The second and third characters are such as have clearly been evolved independently in a number of groups of fishes, while the last appears to be connected with the reduction in the size of the mouth, and is met with (to a slighter extent) in such umrelated genera as Leptolepis, Labeo, and Chatoëssus.

Notopterus, as above mentioned, is a form which has a cartilaginous first basibranchial-the feature is so unaccountable that one seizes upon it as possibly affording a clue to the elucidation of the question of affinity. But the suggestion of close relationship between Gonorhynchus and Noto$p^{t}$ erus is not sustained by a closer examination of the cranial characters, for Notopterus has the right and left parietal bones meeting in the median line, an orbitosphenoid traversed by the cranial cavity, a lateral cranial foramen, an aircontaining vesicle at the side of the occipital region of the cranium, teeth on the parasphenoid, a gape bounded above by both premaxilla and maxilla, no subopercular bone, tendon-bones projecting downward from the posterior end of the second basibranchial, a single hypohyal on each sidecharacters which collectively dissociate this genus from Gonorhynchus.

The Mormyride are a sharply marked family whose
nearest relations are the Notopteridæ, but they are more remote from Gonorhynchus than is Notopterus itself, and may be dismissed forthwith.

The genus Hyodon, while presenting no cranial characters which would negative the possibility of affinity with Gonorhynchus, affords no affirmative evidence. It retains certain primitive characters which have been lost in Gonorhynchus, such, for instance, as the bounding of the upper border of the gape by both maxilla and premaxilla, the mecting of the right and left parietal bones, the presence of teeth on the parasphenoid, the continuation of the cranial cavity through the orbitosphenoid, and the presence of a basisphenoid. So far as the evidence of the characters of the skull bears upon the question, it is not beyond the bounds of possibility that Gonorhynclus should have been descended from some ancestrial branch of the family Hyodontidie, differing from the modern Hyodon in having a smaller supratemporal, in having no air-containing vesicle by the side of the occipital region of the cranium, and in possessing an angular bone distinct from the articular.

None of the characteristic features of the Clupeoid skull are met with in Gonorhynchus. The most striking of such features are the presence of a posterior temporal groove, a temporal foramen, pre-epiotic fossa, auditory fenestra, right and left posterior wings of the parasphenoid, with eye-muscle canal opening between them, and bullate swellings in the squamosal and pro-otic bones for lodging vesicular diverticula of the swim-bladder. No suggestion of any of these is to be found in Gonorhynchus.

Gonorhynchus was by Valenciennes associated with Chanos because of the large size of the branchiostegal membrane and the absence of teeth. It is true that there are several respects in which Chanos differs from the Clupeide proper and approaches Gonorhynchus-such, for instance, as the want of teeth in the jaws, the want of a temporal foramen, pre-epiotic fossa, auditory fenestra, posterior wings of the parasphenoid, and orbitosphenoid and basisphenoid bones, the reduction in size of the mouth, so that the maxilla fails to form part of the boundary of the gape, the absence of surmaxillæ, the separation of the quadrate from the metapterygoid, and the reduction in the number of the branchiostegal rays. But the large size of the posterior temporal fossa and the completeness of its roof are distinctly against the supposition of Valenciennes.

This last objection applies also to the families Elopide
and Albulidæ. They are undoubtedly primitive families, and must have separated early from the common stock of the Telcostean fishes, but one camot regard the forward intrusion of the trunk-muscles as anything but a character of specialization which has been generated subsequently to the severance of these families from the common stem. The ancestral Elopids and Albulids were, of course, upon the line of deseent of the Gonorhynchids, but the relationship is not nearer.

The Stomiatide, in so far as they depart from the primitive type, are specialized in a direction contrary to that along which Gonorlynchus has become modified ; the well-developed maxilla, formidable dentition, wide gill-opening, reduction of opercular skeleton, and presence of a hyoid barbule in the Stomiatide indicate how futile it would be to search for any evidence of close affinity between them and the Gonorhynchidæ.

On comparing the skull of Gonorhynchus with that of Cromeria there is to be noted a similarity in respect of the rod-like form of the metapterygoid and of the palatine (in Gonorhynchus the posterior portion only), the distinctness of the angular from the articular bone, the failure of the first basibranchial to ossify, the smallncss of the number of the branchiostegal rays, and the narrowness of the gill-opening. But against these resemblances there has to be set such a large number of differences as suggests that the allies of Gonorhynchus are not to be sought in the direction of the Cromeriidx. Cromeria, for instance, has the frontal bones widely separated, whereas in Gonorhynchus they are so closely united that the interfrontal suture is obliterated, it has no ectopterygoid, no symplectic, no ascending process of the parasphenoid, no projecting snout, a single hypohyal on each side, no epibranchial organ, a cartilaginous glossohyal, an ossified fourth phargngobranchial, and ossified fourth and fifth basibranchials (see Swimerton, Zool. Jahrb., Abth. Anat. xviii. 1903, pp. 58-70).

Of the two remaining families which I propose to consider -the Alepocephalide and Salmonidx-the former is to a certain extent specialized in relation with its deep-sea habits, but in some respects remains more primitive than the latter. It has no opisthotic, no tecth on the maxilla, an eye-muscle canal closed behind *, and an opercular bone very narrow in

[^45]front; but, on the other hand, it possesses two surmaxillie and an ossified first pharyngobranchial in addition to the spicular. Alepocephalus resembles Gonorhynchus in possessing an epibranchial organ, borne by the fourth and fifth arches, and in possessing a cartilage which may be identified as the fifth epibranchial ; but the list of resemblances is soon exhansted.

On the other hand, the Salmonidx, though offering no close resemblances to the Gonorhynchidæ, consist of a variety of forms but little specialized and highly plastic. For the purposes of comparison the genus Sulmo is less suitable than such a form as Coregomus, for the Salmons have an excess of cartilage, presumably of secondary origin, in the cranium, and no membranous interorbital septum such as Coregomes has. It may be pointed out that within the family Salmonide there are forms, such as Coregonus oxyrhynchus, with prominent snout and reduced mouth with no teeth.

Although a study of the cranial osteology of the Gonorhyuchidæ and Salmonidæ cannot bring forward direct evidence of affinity between these families, the hypothesis of the descent of the Gonorhynchide from the Salmonoid st ck is open to little objection of any serious import. The Salmonidre have an ossified first basibranchial, whereas this element of the copular skeleton fails to ossify in Gonorhynchus; but, as already shown, this basibranchial behaves in its ossification in a most capricious manner in admittedly closely allied genera. The Salmonide have no epibranchial organ ; but this organ, as I have indicated in a former paper (Proc. Zool. Soc. 1904, ii. p. 81), has certainly been evolved independently in a number of different groups of fishes, and in these exhibits such differences in structure and position with regard to the parts of the branchial skeleton that one may reasonably allow that the Gonorhynchidre have developed their epibranchial organ since their separation from the ancestral stock of the Malacopterygii.

XLVI.-Descriptions of some new Species of Noctuida from Tropical South America. By Herbert Druce, F.L.S. \&c.

Lycophotia tetraonis, sp. n.
Female.-Head, collar, tegulæ, and thorax greyish brown; abdomen and legs paler brown. Primaries dark brown, the base and costal margin irrorated with greyish scales ; a submarginal greyish line extends from near the apex to the anal angle, the fringe alternately light and dark brown: secondaries hyaline white, the outer maryin near the apex with a row of fine small black dots. Underside: primaries greybrown, with a marginal row of black dots: secondaries as above, the costal margin irrorated with brown scales.

Expanse $1 \frac{1}{2}$ inch.
Mab. N. Peru: Huancabamba, 6000-10,000 feet (IUus. Druce).

## Mamestra albifluviata, sp. n.

Male.-Front of head black; top of the head and the collar greyish; tegulæ and thorax black; antemme and abdomen black, the base of the abdomen greyish; legs black, banded with white. Primaries white, the inner half black, with a white mark just below the middle, a large $y$-shaped black mark on the costal margin close to the apex, a black spot
about the middle and one nearer the base; the fringe alternately black and white: secondaries white, the apex, costal, and outer margin broadly bordered with pale brown; the fringe dark brown. Underside: primaries brownish black, with four minute white dots on the costal margin near the apex: secondaries white, the costal margin and apex black.

Expanse $1 \frac{1}{4}$ inch.
Hab. Colombia, Honda, 1000 feet (Mus. Druce).
This species is allied to Mamestra albomarginata, Druce.

## Mamestra canosticta, sp. n.

Female.-Head, antennæ, collar, tegulæ, and thorax reddish grey-brown, abdomen and legs paler; a tuft of greyish scales at the base of the abdomen. Primaries reddish brown, thickly irrorated with greyish scales; a marginal row of round grey spots extends from the apex to the anal angle; the fringe reddish brown: secondaries dark brown, the fringe yellowish brown. Underside: both wings pale brown, irrorated with darker brown scales, the secondaries rather paler than the primaries.

Expanse $1 \frac{3}{4}$ inch.
Hab. Bolivia (Garlepp, Mus. Druce).

## Hadena eleistis, sp. n.

Female.-Head, antennæ, collar, tegulæ, and thorax dark brown, the collar and tegulæ edged with pale greyish brown; abdomen reddish brown. Primaries dark brown; the costal margin, veins, and streaks pale greyish brown; a greyishbrown band extends from the apex to the middle of the imner margin; the outer margin pale greyish brown; the fringe dark brown: secondaries semihyaline whitish brown, the veins all dark brown.

Expanse $1_{1-4}^{4}$ inch.
Hab. North Peru, Huancabamba, 6000-10,000 feet (1/us. Druce).

## Hadena œenistis, sp. n.

Female-Head, antennæ, collar, tegulæ, and thorax reddish brown, the tegulæ and collar edged with grey; abdomen greyish brown, the sides reddish brown; anus and leg. reddish brown: primaries dark brown, the costal and inner margin reddish brown; a pale greyish streak extends from the base to the end of the cell ; a narow pinkish-grey band crosses the wing from the apex to the inner margin; a submarginal row of small white spots with black points; the
marginal line greyish brown; the fringe alternately dark and light brown: secondaries dark brown, palest at the base. Underside: primaries dark brown, the outer margin reddish brown: secondaries light reddish brown, whitish in the middle, with a dark brown spot at the end of the cell.

Expanse $1 \frac{1}{2}$ inch.
11ab. Peru, Huancabamba, 6000-10,000 feet (1/us. Druce).

## Nephelistis conservulodes, sp.n.

Femate-Head, antenm, collar, tegulx, and thorax pale reddish brown; abdomen greyish brown; anus yellowish. Primaries dark brown, with a large double V-shaped mark about the middle of the costal margin extending over the wing almost to the imner margin; the $\mathbf{V}$-shaped mark is edged by a fine yellow line; the outer margin from the apex to the anal angle bordered with pinkish brown; a marginal zigzag fine black line from the apex almost to the anal angle: secondaries sordid white, brown at the apex and round the outer margin ; a brown dot at the end of the cell. Underside: primaries blackish brown, the apex and outer margin bright red-brown: secondaries almost the same as the upperside, but paler and redder in colour.

Expanse $1 \frac{3}{4}$ inch.
Hab. Interior of Colombia (Wheeler, Nus. Druce).

## Eriopyga fulvida, sp. n.

Male.-Head, antemne, collar, tegulæ, and thorax pinkish fawn-colour; abdomen pale brown, the anal tuft yellowish fawn-colour; legs and underside of abdomen dark colour. Primaries pinkish fawn-colour, crossed by three very indistinct yellowish lines, the first near the base, the second beyond the cell, the third submarginal ; the fringe fawn-colour: secondaries pale brownish yellow. Underside of both wings very pale yellow, shaded with pink on the costal margins of both wings.

Expanse $1 \frac{1}{2}$ inch.
Mab. South Brazil, Rio (Mus, Druce).

## Eriopyga thermistis, sp.n.

Male.-Head, antennæ, collar, tegulæ, and thorax pale brownish fawn-colour ; abdomen light grey above, the underside and legs reddish brown; the anal tuft yellowish. Primaries pale brownish fawn-colour, the outer margin from the apex to the anal angle dark brown: secondaries yellowish
white, the fringe yellow. Underside: both wings yellowish white, darkest along the costal margins of both wings.

Expanse $1 \frac{1}{4}$ inch.
Hab. Colombia, Sierra del Libane, 6000 feet (II. II. Smith, Mus. Druce).

## Poliodes viola, sp. n.

Female.-Head, antennæ, collar, tegulæ, thorax, and abdomen dark grey, the anus and underside of the abdomen and legs pinkish grey. Primaries dark grey, crossed from the costal to the imer margin by several very indistinct, fine, zigzag, black lines; five small black streaks close to the apex; fringe grey: secondaries white, the veins and outer margins pale brown, the fringe white. Underside: primaries dark grey, shaded along the costal margin and at the apex with pink: secondaries white, the costal margin pinkish.

Expanse 2 inches.
Hab. North Peru, IIuancabamba, 6000-10,000 feet (Nus. Diruce).

## Tmetolophota polygona, sp. n.

Female.-Head, collar, and tegulæ dark brown, edged with pale fawn-colour ; thorax and antennæ brown; abdomen greyish brown, slightly reddish on the underside; legs reddish brown. Primaries pale fawn-colour, with three bands of black streaks edged with yellow between the veins, the first along the costal margin, the second extending from the apex to the middle of the inner margin, the third submarginal near the apex ; the fringe pale fawn-colour: secondaries semihyaline brownish white, the apex and outer margin darker brown; the fringe pale fawn-colour. Underside: primaries dark reddish brown; secondaries pale brownish white, shaded with reddish brown ; a small black dot at the end of the cell.

Expanse 2 inches.
Hab. North Peru, Huancabamba, 6000-10,000 feet (Nus. Druce).
XLVII.-Three new Coleoptera from E. Africa belonging to the Lucanidæ and Cetoniidæ. By Chas. O. Waterhouse.

## Lucanidæ.

Metopodontus Elizabethoc, sp. n.
ठ.-Black. Mandibles rufo-piceous, as long as the head and thorax united, shining, curved downwards from near the
base; with a strong tooth close to the base, a more prominent one at one quarter from the base, a similar one at one third from the apex, and a small one close to the apex. Between the large teeth there are one or two small ones. The head is transversely quadrate, with a slight rounded swelling close to the anterior angle of the thorax ; the upper side is semicircularly impressed, slightly raised in front, with a deep emargination, so as to form two somewhat acute teeth. The head and thorax are both granulose, but the granulation at the side of the head is much stronger than elsewhere. The elytra are yellow, with the suture, the base, and the margins narrowly bordered with black. The tibiæ are pale reddish yellow ; the anterior have a black line along the outer edge, which has a few very small tecth; the middle pair have an acute spine at the middle; the posterior pair are unarmed. The tarsi are reddish, marked with black.

Long. corp. 38-40, mandib. 17-20 mm.
Hab. Usagara, German East Africa (Rev. A. N. Wood).
The smaller specimen has two small teeth about the middle of the left mandible. The larger example has two small teeth about the middle of the left mandible and one similarly placed on the right mandible, and both mandibles have a small tooth before the apical one.

This species is closely allied to M. Savagei, which it represents in E . Africa. It differs in the arrangement of the colour and in the strongly deflexed mandibles.

## Cetoniidæ.

## Dicellachilus, gen. nov.

General form of Compsocephalus. Mentum rather abruptly narlowed in front of the middle, somewhat strongly bilobed in front, with a deep fovea at the base. Sternal process very slightly prominent, obtusely rounded.
o.-IIead with an acute angular projection on each side in front of the eye; a short erect horn in front, compressed at its base, expanded into two retrocurved acute horns at the apex. Forehead with a longitudinal keel, which terminates in front with a slight tubercle. Anterior tibir rather short and broad, furnished with two teeth on the outer edge besides the dentiform apical angle.

ㅇ.-Head with the portion in front of the eyes subquadrangular, gently concave, with a slight keel in the middle, truncate in front, gently simuate. Anterior tibio as in the male.

Dicellachilus Woodi, sp. n.
Black, dull above, shining beneath. Head shining, strongly punctured. Antennæ and palpi pitchy. Thorax convex, dull, broadest just before the base, very slightly narrowed anteriorly for some distance, and then rounded off to the eyes; the posterior angles rounded; the margins beset with short black hair. Elytra orange-yellow, with the suture and margins black; the black at the suture is broad for two thirds its length and then narrows to the apex: the black extends along the base in some examples, and sometimes there is a narrow edging of black at the apex.

Long. 30 mm .
Hab. Usagara, German Eıst Africa (Rev. A. N. Wood).

## Bettonia, gen. nov.

Closely resembles Compsocephalus, but the anterior tibiæ are nearly alike in both sexes, of normal form, armed externally with three acute teeth; the male has sometimes oat or two small teeth on the inner lower side.
or -Forehead with a small tubercle; a small ridge above each eye and a short, transverse, lamelliform horn in front; the lateral margins of the clypeus on each side of this horn flattened, arcuately rounded, as in Compsocephalus. Thorax normal, as in the female. Prosternal process scarcely prominent, obtusely rounded.

## Bettonia mutabilis, sp. n.

Head pitchy red in front, obscure greenish at the back. Thorax, scutellum, and elytra dull, the former obscure greyish or bluish green, the elytra brownish purple. Pygidium rather thickly punctured with transverse punctures; in the male each puncture bears a fulvous hair. Underside shining, entirely blue or variegated with green and purple.
$\delta^{7}$.-Head with a small tubercle on the vertex. Clypeal horn erect, one third broader than high, a little wider at the apex rhan at the base, closely punctured, gently emarginate at the apex. Anterior tarsi not conspicuously longer than in the female.

ㅇ.- Head strongly punctured. Forehead with a very faint indication of the tubercle. Clypeus subquadrate, with angles rounded; the margins slightly reflexed, the anterior margin gently sinuate.

Long. 25 mm .
Hab. Lagari, British East Africa (C. Steuart Betton).
Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.

Var., J.-DEntirely greyish green above. Tuberele on the vertex more distinct, shining. Clypeal hom shorter and relatively broader and less distinctly punctured.

Mlab. British East Africa (A.B. Perciral).

XLTIII.-On some Butrachians and Repites from Tibet. By G. A. Boulenger, F.R.S.
Tue fishes oltained by Lieut.-Col. L. A. Wraddell, C.B., and Capt. H. T. Walton, of the Thibet Frontier Commission, have already been described by my colleague Mr. Regan. I now heg to offer a list of the batrachians and reptiles collected by these gentlemen and preserved in the Natural History Museum.

## Batrachianc.

## 1. Rana Pleskei, Gthr.

Nanorana Fleskei, Guinth. Ammaire Mns. Zool. St. Pétersb. 1896, p. 199; Bedriaga, Przewalski Reis., Zool. iii. i. p. 32, pl. i. fig. 5 (1898).

Numerous specimens were collected by both Lient.-Col. Waddell and Capt. Walton up to an altitude of 15,000 feet. So far only one species of batrachian-Bufo viridis, Laur.was known to occur at such an altitude. The few examples previously described by Guinther and by Bedriaga were obtained in the Province Sze-Chuen and in North-eastern Tibet.

Two small groups of vomerine teeth are sometimes present behind the level of the choanæ, the outer metatarsals are more or less separated by web, at least distally, and a true web does not exist between the fingers. I am therefore unable to accept the genus Nanorana.

Rana Pleskiei is very closely allied to $R$. Blanfordiu, Blgr., the habitat of which is unknown.

## Reptiles.

## 1. Alsophylax tibctanus, sp. n.

Head rather strongly depressed, one and one third as long as bread; snout obtusely pointed, slightly longer than the diameter of the orbit or the distance between the eye and the car-opening; latter moderately large, oval, oblique. Body
depressed. Limbs molerate; digits rather slender; 21 tramsverse lamelle under the fourth toe. Head and body covered with smooth granules, smallest on the occiput; on the back these granules are intermized with numerous irregularly disposed smooth tubereles; ventral scales flat, smonth, subimbricate. Rostral with median cleft above; nostril between the rostral, the first upper lahial, and three nasals; nine upper and seven lower labials; symphysial large, triangular, followed by a pair of large chin-shields. Tail covered with irregular, imbricate, smooth scales. Greyish above, with small dark brown spots and vermiculations, and six crescentic brown, dark-edged cross-bands, the first from eye to eye across the nape, the sixth on the base of the tail ; lower parts white.

A single female specimen from Chaksam Ferry, Tsangpo Valley, 12,500 feet, presented by Lieut.-Col. L. A. Waddell.

## 2. Agama himalayana, Stdr.

Chaksam and Lhasa.

## 3. Phrynocepkalus Theobaldi, Blyth.

Chaksam, Kamba Jong, and Gyangtse.
The black spot on the belly is variable and not a sexual character.
XLIX.-Rhynchotal Notes.-XXXI. By W. L. Distant.

Subfam. Geantines (continued from p. 319).
This communication completes the enumeration of the genera which are included in this subfamily, reserving the inquiry as to a few others which have been described but not yet seen by the writer. These, with any that may come to hand and not yet described, will be referred to when
examined, and their proposed location denoted, as is done in two examples at the end of the present instalment.

## Division Zammararia.

In this division the pronotal margins are ampliated and usually medially angulate; the tympanal orifices are more or less exposed-little in Odopea and very largely in Zammara; the tegmina and wings (with the exception of some species of Odopea) are hyaline and usually more or less spotted.

This division is entirely confined to Tropical and Subtropical America.

## Synopsis of Genera.

| A. Tympanal coverings outwardly complete, the orifices only exposed inwardly. |  |
| :---: | :---: |
| a. Pronotum shorter than mesonotum. |  |

## Genus Odopga.

Odopæca, Stål, Ann. Soc. Ent. Fr. (4) i. p. 616 (1861).
Type, O. dilatata, Fabr. (Tettigoniu).
Odopжа perspicua, sp. n.
Head, pronotum, and mesonotum virescent ; mesonotum with subobsolete traces of four obconical spots on anterior margin, the two central smallest; the anterior margin of the cruciform elevation a little castaneous and greyishly pilose ; abdomen above dark castancous, basally, centrally, longitudinally paler; body beneath and legs greenish ochraccous; tegmina very pale brownish, much suffused and streaked with green, especially on basal half, and with two prominent transverse subcostal spots between radial area and apex; wings pale castaneous, much suffused with dark castaneous on basal and apical areas. Head (including eyes) about as wide as base
of mesonotum ; lateral pronotal margins angularly ampliated ; opercula in male short, not meeting inwardly; tegmina long and narrow.

Long., excl. tegm., 29 mm . ; exp. tegm. 80 mm .
Hab. São Thomé (Negreiros, Paris Mus.).

## Miranha, gen. nov.

Head (including eyes) a little narrower than base of mesonotum, the front moderately prominent, but only about half the length of vertex, lateral margins of vertex a little convex; pronotum about as long as mesonotum, its lateral margins ampliate and medially angulate; abdomen about as long as space between apex of head and base of cruciform elevation, its lateral areas above moderately oblique, the tympanal orifices inwardly covered but outwardly exposed; abdomen beneath with the disk oblique on each side, but with the lateral margins broadly subreflected; rostrum passing the posterior coxæ; opercula small, transverse ; tarsi threejointed; tegmina and wings hyaline, the first with eight apical areas, and the basal cell considerably longer than broad.

Type, M. imbellis, Walk. (Zammara).
Genus Zammara.
Zammara, Amy. \& Serv. Hist. Hém. p. 468 (1843).
'Iype, Z. tympanum, Fabr. (Tettigonia).

## Orellana, gen. nov.

Head (including eyes) only two thirds the width at base of mesonotum, its length about equal to that of pronotum, vertex nearly twice the length of front; pronotum about twice as broad as long, its lateral margins broadly ampliated and medially angulate; mesonotum a little longer than pronotum and (including basal cruciform elevation) about as long as pronotum and head together ; abdomen short, broad, about as long or sometimes shorter than space between apex of head and base of cruciform elevation; tympanal coverings outwardly complete and covering lateral areas, but the orifices widely exposed internally; opercula in male smali, transverse, not passing base of abdomen; face broader than the space between it and eyes; termina and wings hyaline, more or less maculate; tegmina with eight apical areas; tarsi two-jointed.

Allied to Zammara.
Type, O. columbia, Dist. (Zammara).

Orellana brevis, sp. n.
Head, pronotnm, and mesonotum olivaceous green; head with the area of the ocelli, or sometimes completely, shaded with dull castaneous; pronotum with a central fascia and the incisures black; mesonotum with two central obconical spots, on each side of which is a small spot on anterior margin, and a large oblique fasciate spot on each side of posterior disk, black; abdomen above brownish ochraceous ; segmental margins, tympanal coverings, and lateral areas of metanotum bright emerald-green; body beneath and legs pale green; face and apices of tibie and tarsi more or less dull castaneous; abdomen beneath with the stigmata whitishly tomentose; tegmina and wings hyaline, venation fuscous, brownish at base; tegmina with the interior of the basal cell green, costal membrane, a spot at end of radial area, a spot on transverse vein at base of second apical area, and sometimes a spot in upper ulnar area fuscous brown. Head (including eyes) about two thirds the width of mesonotum at base; lateral margins of pronotum strongly ampliate and medially olutusely angulate; lateral tympanal coverings about as broad as the internally exposed orifices; abdomen very short, not longer than space between anterior margin of pronotum and base of cruciform elevation; rostrum reaching posterior coxz.

Long., excl. tegm., オ $24-26 \mathrm{~mm}$. ; exp. tegm. 84-92 mm. Hab. Colombia (Brit. Mus.).

## Division HAmzARIA。

This division, at present including only a single Eastern genus, has much affinity with the Neotropical division Zammararia. The pronotal margins are ampliated; the tympanal coverings only concealing about half of the tympanal orifices; the tegmina and wings almost wholly opaque.

Although the condition of the tympanal oritices allies this division to the Zammararia, with which the dilated pronotal margins also agree, the genus Hamza, on which it is fomeded, could, apart from the tympanal characters, be casily confused with the genus Platypleura belonging to the subfamily Cicadinze.

## Genus Hamza.

Hamza, Dist. Trans. Ent. Soc. Lond. 1904, p. 674.
'Jype, II. bouruensis, Dist. (Platyp?erra).

## Division Geanaria.

This division, at present represented by three Eastern genera, is to be principally recognized by the following characters:-The tegmina and wings are opaque and generally more or less brilliantly coloured; the lateral margins of the pronotum are neither ampliated nor dilated ; the tympanal orifices are largely exposed, the tympanal coverings being a little narrower and much shorter than the orifices, and with their anterior margins convex.

## Synopsis of Genera.

A. Tegmina with the renation normal ; apical areas eight.
a. Head longer than pronotum, front somewhat porrectly produced.
b. Greatest breadth of tegmina more than one third of their length

Gicerthat.
aa. Head not longer than pronotum, obliquely depressed in front of eyes.
bb. Greatest breadth of tegmina only about one third of their length

Balinta.
B. Tegmina with the venation reticulate, ulnar and apical
areas broken up into many cellular divisions
Talainga.

## Genus Geana.

Geana, Amy. \& Serv. Hist. Hém. p. 463 (1843).
Type, G. maculata, Drury (Cicuda).

## Balinta, gen. nov.

Head (including eyes) about as wide as base of mesonotum and as long as pronotum, obliquely depressed in front of eyes; pronotum about as long as mesonotum, its lateral margins sinuate, the posterior angles moderately dilated; abdomen in male much longer than space between apex of head and base of cruciform elevation; tympanal coverings both shorter and narrower than the tympanal orifices, which are most exposed inwardly; opercula in male small and transverse, widely separated, and not extending beyond base of abdomen; rostrum reaching posterior coxa; anterior femora strongly spined beneath ; tegmina and wings opaque; tegmina with their greatest breadth about one third their length and with eight apical areas.
'I'ype, B. octonotata, Westw. (Cicada).

## Balinta auriginea, sp. n.

q. Head, pronotum, and mesonotum yellow; head with some marks at the area of the ocelli and the lateral margins of vertex black ; pronotum with a broad central longitudinal fascia, two large spots on each lateral area, and the lateral margius black; mesonotum with a broad irregular central fascia, a somewhat shorter fascia on each lateral area, and the central base of cruciform elevation, black; abdomen reddish ochraccous, with a central longitudinal fascia, and three large segmental spots on each side, black; body beneath and legs piceous brown; face and space between face and eyes yellow; a large spot near apex of face and a spot at imner margins of eyes black; femora (exclulin. testaccous; tegmina bronzy brown, with three pale spots, two on postcostal area and one at inner angle; some faint pale streaks in the apical areas; wings sanguineous, the apical and posterior margins black.

Long., excl. tegm., of 20 mm . ; exp. tegm. 52 mm .
Hab. Mts. du Ht. Song-Chai (Paris Mus.).
Allied to $B$. octonotata, Westsw.

## Genus Thlainga.

Talainga, Dist. Ann. \& Mag. Nat. Hist. (6) v. p. 166 (1890).
Type, T. Binghami, Dist.

## Division Psithyristriaria.

Head (including eyes) considerably narrower than base of mesonotum, tympanal coverings as long as but very much narrower than the orifices, which are thus inwardly exposed; abdomen narrowed posteriorly, a little longer than the space between the apex of head and base of cruciform elevation; tegmina and wings hyaline: tegmina with the venation abnormal ; apical areas eight, the lower one very small; uhnar areas much compressed, broad, especially the two lowermost.

## Genus Psithyristria.

Psithyristria, Stål, Efv. Vet.-Ak. Förh. 1870, p. 712.
Type, $P$. specularis, Stål.

## Division Xoganniaria.

Tegmina and wing, hyaline, the tegmina spotted or in part more or less brilliantly coloured; boly ovate, more or less attenuated anterionly and posteriorly; head with the front more or less triangularly produced ; tympanal flaps present, but incomplete, the tympanal orifices in part exposed.

Two genera are here included in this division, one Neotropical and the other Oriental in distribution.

## Synopsis of Genera.

A. Anterior femora not spined beneath.
a. Body short and robust; abdomen shorter than pronotum and mesonotum together ; head frontally narrowed and produced.
b. Lateral margins of pronotum dentate.......... Pachypsaltria. B. Anterior femora spined beneath.
aa. Body robust; abdomen a little shorter or almost as long as space between apex of head and base of cruciform elevation; head strongly conically produced.
bb. Lateral margins of pronotum oblique, not dentate. Mogunnia.

## Genus Pachypsalthia.

Pachypsaltria, Stål, Ann. Soc. Ent. Fr. (4) i. p. 616 (1861).
Type, P. cincto-maculata, Stål (Cicada).

## Genus Mogannia.

Mogannia, Amy. \& Serv. Hist. Hém. p. 467 (1843).
Type, M. conica, Germ. (Cicada).

## Nogannia mandarina, sp. n.

i. Body and legs black, sliming; head, pronotum, and mesonotum somewhat longly ochraceously pilose ; abdomen above with a broad central, longitudinal, ochraceously pilose fascia; underside of body and legs somewhat less longly pilose; tegmina and wings hyaline, the venation piceous; tegmina with the basal half shining black, containing a transverse hyaline fascia divided by the dark veins, occupying basal half of radial area and terminating beneath basal cell; head with the front longly produced, its apex terminating in a tuft of long ochraceous hairs.

Long., excl. tegm., if 18 mm .; exp. tegm. 45 mm .
Hab. Hong Kong (Brit. Mur.).
Allied to M. nusalis, White.

## Mogannia Horsfeldi, sp. n.

q. Head, pronotum, and mesonotum very thickly ochraceously pilose; abdomen above black, with a broad, central, longitudinal, ochraceously pilose fascia; body beneath and legs piceous, the first thickly and the legs sparingly ochraceously pilose; tegmina and wings hyaline, extreme bases of both reddish ochraceous, the venation brownish or piceous; tegmina with the basal half connected at posterior angle with a very broad submarginal fascia, piceous brown; wings with the basal area beyond the reddish-ochraceous base pale fuscous.

Long., excl. tegm., if 15 mm .; exp. tegm. 36 mm . Hab. Java (Horsfield, Brit. Mus.).

## Addenda.

Division Cicadatraria (ante, p. 304).

> Tamasa, gen. nov.

Body moderately short, abdomen not longer than space between apex of head and base of cruciform elevation; tympanal coverings both narrower and shorter than tympanal cavities; head shorter than pronotum, which is slightly shorter than mesonotum.

A genus intermediate between Tettigia and Terpnosia. From Tettigia it is separable by the structure of the tympanal coverings, which are both narrower and shorter than tympanal cavities, and by the short abdomen ; from Terpnosia it also differs by the short and opaque abdomen, the greater width of the head between cyes $=$ to width of base of mesonotum, and by the tympanal coverings being subangulate anteriorly.

Type, T. tristigma, Germ. (Cicada).

## Subfam. Cicadines.

> Division Heteropsaltriaria (to follow Cicadaria, vol. xiv. p. 42.5 ).

This division, at present represented by a single genus, is to be distinguished from the Cicadaria by the distinet venation of the tegmina, the radial area being very large and
broad, considerably more than half the whole length of tegmina, which has brought about the shortening of the three $p$ per ulnar areas.

## Genus Heteropsaltria.

Heteropsaltria, Jacobi, SB. Ges. naturf. Fr. Berl. 1902, p. 73.
Type, II. aliena, Jacobi.

## L.-New Ground-Squirvels of the Xerus erythropus Group. By Oldfield Thomas.

In working out some ground-squirrels from Lake Chad presented by Capt. G. B. Gosling to the British Museum I have examined all the specimens assigned to Xerus erythropus, and find that, although very similar throughout the vast range of the group, they can be divided into two species by the size of their premolars, the East-African animal having these teeth noticeably smaller than in the other cases.

Of each of these two species again there is evidence of several geographical subspecies, so that six forms are distinguishable, as in the following synopsis:-
A. Posterior upper premolar large, subquadrangular.
a. Back near clay-colour ; forearms buff.
$a^{2}$. West Africa .......................... X. erythropus, Geoff.
$b^{2}$. Abyssinia and Egyptian Soudan ......... X. e. lencoumbrimus,
b. Colour lighter; back near "pinkish buff"; furearms "cream-buff." Lake Chad ....
c. Back blackened, approaching "mummybrown"; forearms "cimnamon." Unyoro.
B. Posterior upper premolar small, cylindrical.
a. 13ack dull clay-colour; forearms dull buffy .
b. Lack tawny ochraceous; forearms between "ochraceous" and "clay-colour".........
[Rüpp. X. e. chadensis,

Lsubsp. n.
X. c. lacustris,
[subsp. n.
X. microdon, sp. n.
[subsp. n.
X. m. fulvior,

All the current synonyms of $X$. erythropus are West African and reterable to the typical subspecies, except Rüppeli's leucoumbrimus, which will stand for the very similar Soudanese and Abyssinian animal.

Xerus erythropus chadensis, subsp. n.
Similar in general characters to Upper Nile cxamples of X. e. lucoumbrinus, but the colour much lighter throughout.

General dorsal area between "pinkish buff" and "buff," lightening on the limbs to "cream-buff." Head and foreback less uniform, more heavily lined with blackish. Intermediate band between the white lateral line and the white of the belly darker than the general coluur, more or less mixed with blackish. Under surface very short-haired, partly naked in the axillary and inguinal regions, white. Upper surface of hands and feet cream-buff. Short-haired part of tail darker buffy. Long hairs of tail, as seen from below, buff basally, oceasionally approaching ochraceous buff, then cream-buff, with a subterminal ring of black and a broad cream-buff tip. In $X$. e. leucoumbrinus the basal part of the tail-hairs is ordinarily "ochraceous buff" or even " ochraceous."

Skull apparently quite as in leucoumbrinus, the posterior premolar proportionally large; rounded-quadrangular, not small as in the East-African species.

Dimensions of the type (measured in the flesh) :-
Head and body 262 mm . ; tail 240 ; hind foot 63.
Skull: greatest length $61 \cdot 7$; basilar length 49 ; zygomatic breadth 33 ; palate length from henselion 30.3 ; front of large premolar to back of $m^{3} 11 \cdot 3$; breadth of large premolar $3 \cdot 5$.

Hab. Yo, Lake Chad.
Type. Adult male. Original number 44. Collected 11th October, 1904, and presented by Capt. G. B. Gosling. Four specimens.

Xerus erythropus lacustris, subsp. n .
Colour darker than in any of the allied forms, the back heavily blackened, so as nearly to match Ridgway's "mummybrown." Crown still darker, glossy blackish, speckled with buffy. Area below white lateral line broader than usual, fincly speckled blackish. Under surface even more thinly haired than usual, dull buffy whitish along the middle line, the sides of the belly buffy, as are the inner sides of the limbs and the upper surface of the hands and feet. Forearms dark ochraceous clay-colour. Hairs of upper side of tail black at their bases, those of the lower side ochraceous buff basally.

Skull with the large premolars characteristic of X. erythropus, contrasting in this respect with the geographically allied $X$. microdon.

Dimensions of the type:-
Head and hody 305 mm . ; tail 240 ; hind foot 64 .

Skull: greatest length 6t; basilar leugth 50 ; zygomatic breadth $32 \cdot 5$; palate length from henselion $30 \cdot 3$; front of large premolar to back of $m^{3} 12$; breadth of posterior upper premolar 3.8.

Hab. Masindi, Unyoro.
Type. Adult female. B.M. no. 2. 11. 1. 5. Collected 23rd June, 1897, by Dr. W. J. Ansorge.

An isolated skull and two young skins collected by Emin Pasha in Monbuttu appear also to be referable to this form.

## Xerus microdon, sp. n.

General colour above tawny clay-colour, becoming more blackish on the crown and muzzle, more ochraceous on the base of the tail. White markings as in X. erythropus. Dark area below lateral line blackish brown. Sides of belly and inner sides of limbs washed with pale buffy. Forearms dull buffy. Upper surface of hands and feet cream-buff. Bases of tail-hairs strong ochraceous buff.

Skull as usual. Posterior upper premolar comparatively small, cylindrical.

Dimensions of the type (measured on the skin) :-
Head and body 285 mm . ; tail 225 ; hind foot (wet) 63.
Skull: greatest length 62 ; basilar length 49 ; zygomatic breadth 33 ; palate length from henselion 29 ; front of large premolar to back of $m^{3} 12$; diameter of large upper premolar 3.

Hab. British East Africa. Type from Kitui, alt. 1000 m. ; other specimens from Ukambani (Jackson).

Type. Adult male. B.M. no. 1.2.5.4. Original number 51. Collected 20th September, 1900, and presented by S. L. Hinde, Esq.

## Xerus microdon fulvior, subsp. n.

Similar in all essential characters to true microdon, but the colours richer, darker, and more tawny throughout. Back tawny ochraceous, becoming deep rufous on rump ; hands, wash along sides of belly, hind limbs, and top of teet ochraceous buff instead of buffy or cream-buff. Forearms between ochraceous and clay-colour. Bases of tail-hairs dark tawny.

Dimensions of type :-
Head and body 295 mm . ; tail (imperfect); hind foot 62 .
Skull: greatest length 64.5 .

Hab. Fort Hall, Mt. Kenya district. Alt. 1300 m .
Type. Adult male. B.M. no. 3. 11. 1. 4. Original number 170. Collected 10th June, 1903, and presented by S. L. Hinde, Esq. Tiso specimens.

LT.-A new Subspecies of Glossina palpalis, Rob.-Desv., the Disseminator of Sleeping Sickness. By Ernest E. Austen.

Tire British Museum has just received from Dr. F. Creighton Wellman, of Benguella, W. Africa, some specimens of a tsetse-fly which, though obviously belonging to Glossina palpalis, Rob.-Desv., are sufficiently distinct from the typical form to be regarded as representing a new subspecies, which may be termed Glossina palpalis Wellmani, subsp. n.
'I'he new subspecies may be characterized shortly as follows, by indicating the points in which it differs from the typical form :-

> Glossina palpalis Wellmani, subsp. n.
of ㅇ.-Frontal stripe pale ochraceous; thoracic markings much reduced, so that the thorax in a well-preserved specimen appears spotted, the antero-lateral markings taking the form of spots or blotehes; the spot immediately behind the inner extremity of the humeral callus on each side small, ovoid, or nearly circular, and especially conspicuous when the insect is viewed from above and slightly from behind; femora pale, the dark blotches much reduced.

Katumbela River, Angola, W. Africa; November 1904 (Dr, F. C. Wellman). Six specimens ( 1 of, 5 ㅇ if). Types in British Museum.

Writing from Benguella, under date Feb. 5, 1905, Dr. Wellman says:-"I took about eighty specimens of these tsetse-flies in four days along the banks of the Katumbela River, two days from the coast, in the height of the rainy season."

The above specimens are of especial interest as being the first recorded examples of any form of Gll. palpalis from Portuguese West Africa and as showing that the range of the species in question, which has recently been stated by Laveran * to occur at Sengaleam (about thirty miles from

[^47](ape Verde), extends at least as far south as $12^{\circ}: 30^{\prime} \mathrm{S}$. lat. In all probability Glossina palpalis Wellmani will eventually be proved to exist right down to the Cmmene River, the southern boundary of Angola, if not further; and it is to be hoped that evidence to decide the southern limit of $G l$. palpulis will shortly be forthcoming.

In conclusion, it may be remarked that the British Mnseum possesses two females of Gl . palpalis from the Gambia (Dr. J. E. Dutton), belonging to a form somewhat similar to Wellmani ; in the Gambia form, however, the ground-colour of the abdomen is paler and the thorax is less conspicuously spotted.

## LH.-The Bonin Island Samber. By R. Lydekiker.

The most northerly limit in the Pacific for deer of the sambar group has been supposed to be Formosa, from which we have Cervus Suinhoei, or, as I prefer to call it, C. unicolor Swinhoei. I have lately, however, had the opportunity of inspecting two specimens of sambar from Bonin Island, lying about one degree to the east-south-east of the southern end of Japan. One specimen is the skull of a female acquired by the late Mr. H. Seebohm in 1889, and presented by his executors to the British Museum in 18:30 (96.2.25.4). The second is the skin, skull, and antlers of a male belonging to Mr. Rothschild.

That the Bonin deer is a sambar is shown not only by Mr. Rothschild's specimen, but likewise by the female skull, which exhibits the proximally expanded masals, the deep lachrymal pit, and the small auditory bulla characteristic of that group.

The female skull, which is fully adult and has a basal length of $8 \frac{3}{4}$ inches, indicates a species of the approximate size of the dusky Philippine sambar (C. u. nigricans), and therefore much smaller than the Formosan animal. Certain details in the form and relations of the nasals and premaxillæ distinguish the Bonin skull from two specimens of that of nigricans, but I have no means of ascertaining whether such features are constant. Be this as it may, the Bonin sambar differs from rigricans by the much lighter colour of the under-parts and limbs, there being a sharp line of demarcation between the brown of the back and the rufous fawn of the
flanks, while the lower segment of the limbs is nearly white. The tail, too, is shorter and white below, instead of uniformly dusky.

It is thus obvious that in respect of colom the Bonin deer comes much nearer to the Formosan than it does to the dusky Philippine sambar (I have not a specimen of the larger Luzon sambar with which to compare it). Accordingly, for all I can say to the contrary, it may be an imported breed of the Formosan sambar, dwarfed by the small area of its habitat. But as there is no evidence of this, it may be provisionally regarded as a distinct island race under the name of Cervus (Tiusa) unicolor boninensis, with the female skull in the British Museum as the type.
> LIII.-On the South-African Curculionide of the Genus Cossonus, Clairv. By Guy A. K. Marshall, E.Z.S.

The genus Cossonus has practically a world-wide distribution, but, as at present known, is better represented in America than anywhere else. Only eight species have hitherto been recorded from Southern Africa, and six more are described in the present paper. But even with this increase it seems probable that the number of South-African species might readily be doubled when the area is more thoroughly worked. The timber-belts of the Transkei and Pondoland, the yellowwood forests of Natal, the heavily wooded regions which adjoin the eastern littoral from Zululand northward into the tropics, are all practically virgin ground for the colcopterist, and when adequately explored will doubtless yield many new forms.

These insects seem, as a rule, to be but poorly represented in collections, for unless specially searched for they are not likely to be met with by the casual collector. All our species with whose habits I am acquainted live under the bark of decaying trees; but they seem to require damp surroundings, and thus in the drier parts of the country they are only to be found in trees which are subject to moist decay, such as Euphorbias and a few soft-wooded species like the Erythrinas. In these latter I have only found them when the trees were being killed by the attacks of certain Longicorn or Buprestid larve, the Cossoni being usually found in the moist decaying matter left in the tracks of these larva just beneath the bark. With them also occur a few other Curculionidæ, such as

Corynemerus, Phlcoophagus, \&c., as well as various Nitidulidæ, Staphylinidæ, and some dipterous larve. These in turn attract the predaceous Histeridre of such genera as Iololopta, Pachycrerus, Placodes, and Epiechinus, which doubtless prey on the Cossoni as well as on the other insects.
It will probably be found that most of the species have a fairly wide distribution. This is certainly the case with C. abscissus, Boh., which ranges from Algoa Bay to the Equator and across the continent to Camerum. C. suturalis, Boh., has also been found both in Natal and on the ('ongo, but has not hitherto been recorded from any intermediate localities.

Synoptic Key for the Soutlh-African Species of Cossonus.

1. (24.) Rostrum more or less strongly dilated in the apical halt'.
2. (7.) Interrals on elytra bearing rows of punctures.
3. (4.) Pruthorax very deeply incised near apex, bipartite; the intervals near the suture carinate, much narrower than the strice
4. C'. abscissus, Boh.
5. (3.) Prothorax simply constricted near apex, not incised; the intervals near the suture plane, as broad as the striæ.
6. (6.) Prothorax without any discal impressious or a central carina; rostrum very gradually dilated from base to apex..
7. C'. Sheppardi, sp. n.
8. (5.) Prothorax with a distinct carina and a longitudinal basal impression on each side of it; rostrum suddeuly and very strongly dilated at apex . .............
9. (2.) Intervals on elytra impunctate.
10. C. carinicollis,
[Fahr.
11. (21.) Prothorax distinctly impressed or carinate on the disk.
12. (20.) Rostrum without any central furrow above.
13. (19.) Elytra with only 9 complete strire and a short subhumeral one; the central impression on prothorax not interrupted transversely.
14. (14.) Prothorax with the smooth discal areas finely and sparsely punctured.
15. (13.) Prothorax subpyriform, the sides gradually dilated from apex to beyond middle; metasternum evenly but sparsely punctured
16. C'. africames, Boh.
17. C. incivilis, Führ.

Ann. \& Llay. N. Hist. Ser. 7. Vol. xv.
14. (11.) Prothoras with the smooth discal areas impunctate.
15. (18.) Forehend with a distinct central fovea; central carina of prothorax very narrow, obsolete or incomplete.
16. (17.) Forchead with a shallow transverse impression; thoracic impression narrower, deeper, more sharply V-shaped, and without a central carina; elytra black.
17. (16.) Forehead without a transverse impression; thoracic impression broader and shallower, and with an irregular central carina; elytra ferruginous brown, with the suture and lateral margins black
6. C. transvaalensis,
[sp. n.
7. C. suturalis, Boh.
18. (15.) Forehead with no central fovea; central carina of prothorax complete, broad and impunctate
8. C. umzila, sp. n.
21. (8.) Prothorax plane and smooth, without a carina or any distinct impressions; body much depressed.
22. (23.) Rostrum longer than head and only slightly dilated; head short, subconical; elytra with 9 shallow strix, the intervals being broad and plane.
23. (22.) Rostrum shorter than head and broadly dilated; head elongate, subquadrate; elytra with 10 deep strix, the intervals narrow and subcarinate
12. C. complanatus,
24. (1.) Rostrum subcylindrical, not dilated at apex.
25. (26.) Rostrum impunctate dorsally; central impression on prothorax at base only, the median carina indistinct anteriorly. 11. Cdglabricollis, Boh.
[sp. n.
9. C. chirindensis,
20. (9.) Rostrum with a central furrow at base .
10. C. elongatulus, F.
19. (10.) Elytra with 10 complete striz; the central impression on prothorax transversely interrupted about middle ....
anteriorly, with distinct confluent punctuation and occasionally a faint central carina ; antenna inserted about middle, piceous. Prothorax bipartite, longer than broad, apex truncate and much narrower than base, which is deeply bisinuate; a very deep constriction near apex; the posterior portion slightly convex, evenly set with large deep punctures and with an obsolete median carina; the anterior portion somewhat raised and much less coarsely punctured ; colour dull black, bare. Elytra separately rounded at base, a little broader than prothorax at shoulders, which are sloping, sides subparallel to beyond middle; upper surface slightly convex, with only eight complete strix, containing rows of very large and deep foveole, the third and fourth rows each divided into two at base by narrow carinæ extending only a short distance, the intervals very narrow, each with a row of indistinct and distant punctures bearing minute setæ, which can only be perceived with difficulty; colour dull black. Legs closely punctured and with sparse pale pubescence, femora black, tibiæ and tarsi piceous.

Cape Colony: Algoa Bay (Dr. H. Brauns) ; Natal: Malvern (C. N. Barker) ; 'Transvaal: Leydenburg (Dr. J. W. B. Gunning) ; Mashonaland: Victoria.
'Type missing; in Ecklon and Zeyher's collection.
This species may be readily recognized from all its SouthAfrican congeners by the structure of the thorax. The only specimen I have taken was found under the bark of a large dead acacia. The species has been recorded by Faust from Camerun and by Gerstaecker from Arusha in German East Africa. Some specimens are covered with a fine earthy indumentum, which can be made to scale off ; it is not quite clear whether this is a natural covering or merely adventitious.

## 2. Cossonus Sheppardi, sp. n.

Long. 5-6, lat. $1 \frac{1}{5}-1 \frac{1}{2} \mathrm{~mm}$.
Head subconical, almost impunctate on vertex, forehead closely and coarsely punctured and with a small central fovea, each puncture being filled with a short, depressed, scale-like, white seta; eyes prominent. Rostrum stout, about as long as head, scarcely curved, gradually dilated from base to apex; upper surface plane, with punctures and setæ similar to those on forehead ; antennæ ferruginous, inserted in front of middle. Prothorax longer than broad, apex trancate, base faintly bisinuate, sides slightly rounded, broadest rather behind middle and strongly constricted near apex ; upper surface slightly convex, without any central furrow or
carina, evenly set with large shallow punctures, each containing a very short white seta; colour dull black. Elytra subtruncate at base, a little broader than prothorax at shoulders, which are rounded, sides subparallel to beyond middle; upper surface somewhat convex, with ten complete strie containing deep closely-set punctures, the intervals plane, as broad as the strise near the suture, but those between the third and fourth strix and between the fifth and sixth are very narrow and uneven, so that the punctures in these strix are respectively approximated and often irregular or even more or less confused together (TYPE form); the broader intervals have each a row of small but distinct and close punctures bearing minute depressed white sete; colour dull black. Legs punctate, with scattered depressed white setæ, piccous, with the tarsi ferruginous.

Portuguese E. Africa: Beira (P. A. Sheppard).
Type in the British Museum.
Allied to C. abscissus, Boh., from which it differs, however, in many characters. Its nearest ally is C.torvidus, Boh., from Senegal, but the latter, which is a more robust insect, has its rostrum very strongly and quadrangularly dilated at the apex and with a low central carina; the thoracic constriction is similar, but the basal margin is more deeply bisinuate, and the intervals on the elytra are much more coarsely punctured.

I have much pleasure in dedicating this species to Mr. P. A. Sheppard, of Beira, to whom I am indebted for much valuable material from that hitherto unworked locality.

## 3. Cossonus carinicollis, Fåhr.

Cossonus carinicollis, Fåhr. Efv. K. Vet.-Akad. Förh. 1871, p. 284.
Long. 5-S, lat. $1 \frac{1}{2}-2 \frac{1}{2} \mathrm{~mm}$.
Head subconical, closely and strongly punctured ; forehead with a deep central fovea; eyes slightly prominent. Rostrum rather longer than head, parallel-sided to about middle, thence abruptly and quadrangularly dilated ; upper surface plane, closely and distinctly punctured, but with a variable impunctate median line or patch; antenne inserted near apex. Prothorax scarcely longer than broad, apex truncate and much narrower than base, which is slightly bisinuate, sides moderately rounded, broadest at middle, slightly constricted at apex, posterior angles with a very small acute projection; upper suface almost plane, closely and distinctly punctured throughout, and with a smooth central carina, which has a broad shallow impression on each side at base ; colour black
or ferruginous, with carina and margins black. Elytra a little broader than prothorax at shoulders, which are sloping, base subtruncate, sides parallel to beyond middle; upper surface slightly convex, with ten complete broad stria containing rows of large deep punctures, the intervals narrow, subconvex, minutely punctulate; colour eithor black or ferruginous, with the suture and margins black or entirely ferruginous. Legs comparatively long, closely punctulate and sparsely pubescent, varying in colour from black to ferruginous.

Natal: Durban.
Type in the Stockholm Muscum.
Much the largest of our South-African species and with no near ally.

## 4. Cossonus africanus, Boh.

Cossonus africanus, Boh. Schön. Gen. Curc. viii. 2, p. 272 (1845).
Long. $4-4 \frac{1}{2}$, lat. $1 \frac{1}{4}-1 \frac{1}{2} \mathrm{~mm}$.
Head subconical, vertex impunctate, forehead finely punctured and with a distinct fovea; eyes slightly prominent. Rostrum scarcely longer than head, narrow and subcylindrical at base, strongly and quadrangularly dilated in the apical half; upper surface smooth, flattened towards apex, with fine scattered punctuation ; antennæ stout, ferruginous. Prothorax about as long as broad, apex truncate, much narrower than base, which is lightly bisinuate, sides slightly rounded, and gradually dilated from apex to just behind middle, apex with a slight constriction; upper surface somewhat convex, with a distinct central carina and a shallow longitudinal impression on each side of it; the punctures are close and deep near the carina, becoming finer on the disk and stronger again towards the sides; colour black, shining. Elytra separately rounded at base, a little broader than prothorax at shoulders, which are roundedly prominent, sides parallel to beyond middle; upper surface slightly convex, with 9 complete fine strice containing rows of small closely-set punctures, the intervals comparatively broad, almost plane, impunctate, but faintly coriaceous; colour black, moderately shining. Legs piceous, bare, finely punctate; tibiæ and tarsi ferruginous.

Cape of Good Hope (Wuhlberg), Cape 'Jown (A. Raffray).
'Type in the Stockholm Museum.
The punctuation of the discal areas of the prothorax is variable, being much closer and more distinct in some specimens. These latter are thus not unlike very small
examples of C. elongatulus, F., in general appearance; but the rostral structure of that species is very different and the elytra are more deeply striate.

## 5. Cossonus incivilis, Fåhr.

Cossonus incivilis, Făhr. ©efv. K. Vet.-Akad. Förh. 1871, p. 286.
Long. 4-4 $\frac{2}{5}$, lat. $1 \frac{1}{5}-1 \frac{2}{5} \mathrm{~mm}$.
Head subconical, impunctate on vertex, forehead punctulate and with a variable central fovea; eyes rather large, slightly prominent. Rostrum about as long as head, narrowing gradually from base to middle, thence broadly and quadrangularly dilated to apex; upper surface even, closely and finely punctured; antemæ short and stout, ferruginous, inserted in front of middle. Prothorax rather longer than broal, apex truncate and much narrower than base, which is strongly bisinuate, sides slightly rounded, breadest about middle, faintly constricted at apex; upper surface slightly convex, with a strong central impression, narrow from near apex to middle, thence broadly and triangularly dilated to base, the anterior part being usually shallow; the impression is strongly punctured and contains a very narrow undulating carina, the disk smooth and with very fine sparse punctuation, beyond which the sides are deeply and coarsely punctured; colour black, shining. Elytra separately rounded at base, very little broader than prothorax at shoulders, which are sloping, sides parallel to beyond middle; upper surface moderately convex, with nine complete strongly punctured strix, which are very deep near the suture, but become shallower laterally, intervals almost as broad as strix, convex and impunctate; colour black, shining. Lrgs short, piccous, bare, and obsoletely punctured, tarsi paler.

Natal: Verulam, Umgeni ; Mashonaland: Salisbury.
Type in the Stockholm Museum.
The typical specimens taken by Wahlberg in "Caffraria" are apparently immature, all my own examples being of a shining black colour. The species in general form and sculpture is allied to suturalis, Boh., and transvaalensis, Mshl., but it is distinctly more convex, the rostrum is much more dilated and more evidently punctured above, and the thoracic impression is of a different shape.

In Natal I found this insect in decaying Euphorbias, and at Salisbury under the rotting bark of what is locally known as the " cabbage-tree."

## 6. Cossonus transvaalensis, sp. n.

Long. $3 \frac{3}{4}$, lat. 1 mm .
Head subconical, black, shining, impunctate, with a distinct shallow transverse impression benind the eyes; foreheal with a small central fovea; eyes slightly prominent. Rostrum about as long as head, moderately curved, cylindrical at base, thence gradually dilated and flattened towards apex, upper surface with very fine faint punctuation, the sides coarsely punctured; antenne ferruginous, inserted about mildle. Prothorax a little longer than broad, sides slightly rounded, broadest about middle, constricted near apex, base bisinuate; upper surface plane, with a deep, sharply defined, V-shaped central impression, which is filled with coarse punctures and has no distinct central carina; discal area impunctate, the sides closely and deeply punctured; colour black, glabrous. Elytra rounded at base and scarcely broader than the thorax, shoulders rounded, sides parallel to beyond middle; upper surface slightly convex, scarcely striate except close to base, but with nine complete rows of deep separate punctures, which are smaller apically and laterally, the intervals plane and impunctate; colour black, shining, glabrous. Legs piceous, obsoletely punctured.

## Transvaal.

Type in the British Museum.
Nearly allied structurally to C. suturalis, Boh., but the present species is a distinctly narrower and slightly more convex insect, and, in addition to the characters mentioned in the key, it may be distinguished by the coarser punctuation of the rostrum and the difference in the striation of the elytra.

## 7. Cossonus suturalis, Boh.

Cossonus sutaralis, Boh. Schön. Gen. Curc. iv. p. 1033 (1838).
Long. 4-5, lat. 1-1 $\frac{3}{4} \mathrm{~mm}$.
Head subconical, black, glabrous, minutely punctured, and with a deep oblong fovea on forehead; eyes slightly prominent. Rostrum about as long as head, very little curved, sides subparallel at base, apical half with a slight quadrangular dilatation; upper surface impunctate, the sides faintly punctured; antennæ ferruginous, inserted well in front of middle. Prothorax a little longer than broad, sides slightly rounded, broadest behind middle, apex distinctly constricted, base gently bisinuate; upper surface depressed, with a broad central impression, gradually dilated from near apex to base and filled througbout with large confluent punctures, except
for a smooth central line of variable width ; discal area impunctate, the sides closely and strongly punctured ; colour black, glabrous. Elytra subtruncate at base and scarcely broader than thorax, shoulders slightly prominent, the sides very gradually narrowed from base to apex; upper surface depressed, with nine complete strongly punctured strix, which are deep and crenato-punctate on disk, but very shallow laterally, the intervals plane but narrow and impunctate; colour ferruginous brown, with the suture and apex broadly, the lateral margins narrowly black. Legs black, shining, obsoletely punctured, tarsi piceous.

Natal: Durban, Verulam.
Type in the Stockholm Museum.
A common species occurring in some numbers under the rotting bark of several soft-wood trees, and especially the Kafir boom (Erythrina caffica). Also recorded from the Congo by Faust.

## 8. Cossonus umzila, sp.n.

Long. $3 \frac{1}{2}-4$, lat. $1-1 \frac{1}{4} \mathrm{~mm}$.
Head subconical, vertex impunctate; forehead closely and finely punctured, but without any central fovea; eyes prominent. Rostrum longer than head, subcylindrical at base, distinctly though not broadly dilated in the apical half; upper surface convex, shining black, with extremely fine punctuation; antenne inserted near apex, ferruginous. Prothorax scarcely longer than broad, apex truncate, base bisinuate, sides subparallel to about middle, thence rapidly narrowed to apex, where there is a slight constriction ; upper surface plane, with a broad, decp, triangular impression extending from the apical constriction to base, the impression being rugosely punctured and containing a broad impunctate carina throughout; the portions of the disk adjoining the central impression are quite smooth and impunctate, but the sides are very coarsely punctured; shining black, bare. Elytra separately rounded at base, a trifle broader than prothorax at shoulders, which are sloping, sides subparallel to beyond middle; upper surface plane, subdepressed, with nine deep strongly punctured strix, the tenth stria being subhumeral and much abbreviated, the intervals narrow, carinate, and impunctate. Legs piceous black, shining, bare, impunctate ; tarsi ferruginous.
S.E. Mashonaland: Chirinda Forest.

Type in the British Museum.

## 9. Cossonus chirindensis, sp. n.

Long. $5-5 \frac{3}{4}$, lat. $1 \frac{1}{4}-1 \frac{1}{2} \mathrm{~mm}$.
Head subconical, impunctate on vertex ; forehead fincly punctured and with a deep elongate fovea; cyes prominent. Rostrum scarcely longer than head, sinuate laterally in the middle, broadly and subquadranjularly dilated at apex; upper surface closely and finely punctured, almost plane apically ; anteme ferruginous, inserted quite close to apex. Prothorax broader than long, apex truncate, much narrower than base, which is bisinuate; sides subparallel to about middle, then gradually narrowed to apex, where there is a slight constriction; upper surface almost plane, very fincly punctured on the disk, but coarsely so towards the sides, with a shallow longitudinal impression close to apex containing an ill-dufined central carina, with a few large punctures on each side of it, and a much deeper trapezoidal impression at base, which is rugosely punctured and contains a distinct narrow carina, the two impressions being separated by a narrow smooth space; colour uniform light testaceous brown. Elytra separately rounded at base, broader than the prothorax at shoulders, which are roundedly prominent, sides subparallel to beyond middle; upper surface plane, with ten complete, deep, and strongly punctured strix, the intervals being narrow, convex, and impunctate; colour uniform testaceous brown, a little darker than the prothorax. Legs testaceous, bare, and finely punctured.
S.E. Mashonaland: Chirinda Forest.

Type in the British Museum.
This species, as also C. umzila, I captured flying in the daytime along shady paths in the dense forest.

## 10. Cossonus elongatulus, Fab.

Curculio elongatulus, Fab. Ent. Syst., Suppl. p. 168.
Cossonus elongatulus, Boh. Schön. Gen. Curc. iv. p. 1022 (1837).
Long. $3 \frac{1}{2}-6 \frac{1}{2}$, lat. $1-2 \mathrm{~mm}$.
Head subconical, piccous, shining, impunctate on vertex; forehead with fine scattered punctures; eyes slightly prominent. Rostrum stout, a little shorter than head, broad and flattened; sides parallel in the basal half and with a slight quadrangular dilatation at apex, black or ferruginous, shining, deeply punctured, and with a broad central furrow, which ascends the forehead, but is abbreviated anteriorly; antennæ stout, ferruginous. Prothorax longer than broad, apex truncate, much narrower than base, which is subbisinuate,
sides gently rounded, broadest about middle, rapidly narrowing towards apex, where there is a slight constriction; upper surface almost plane, deeply and closely punctured, with a slightly raised smooth central line and a faint longitudinal impression on each side of it ; colour entirely black or ferruginous, with the sides and under surface sometimes blackish. Elytra subtruncate at base, a little broader than the prothorax at shoulders, which are subrectangular, sides parallel to beyond middle; upper surface almost plane, with deep and strongly punctured strix, the intervals narrow and impunctate; colour entirely black or ferruginous, the suture and lateral margins being more or less infuscate. Leys short, rather slender, with faint scattered punctuation, black or ferruginous, with the knees rather darker.

Cape of Good Hope (teste Boheman) ; S.E. Mashonaland: Chirinda Forest.

I am not aware of the existence of Fabricius's type of this species; but the specimens upon which Boheman founded his description are in the Stockholm Museum.

Boheman also records the insect from India and Mauritius.
With the exception of C. abscissus, Boh., which differs widely in other respects, this is the only South-African species with a furrow on the upper surface of the rostrum.

## 11. Cossonus glabricollis, Boh.

Cossonus glabricollis, Boh. op. cit. iv. p. 1034 (1838).
Long. 4, lat. $1_{2}^{1} \mathrm{~mm}$.
Head conical, shining, impunctate, with a minute fovea on forehead and slightly constricted behind the eyes, which are subdepressed. Rostrum longer than head, curved, subcylindrical at base, slightly and quadrangularly dilated apically ; smooth, shining, and almost impunctate ; antennex comparatively long, ferruginous, inserted in front of middle. Prothorax broadest at base, gradually narrowed till close to apes, where there is a slight constriction, apex truncate, base bisinuate, posterior angles with a minute sharp projection; upper surface plane, smooth, shining black, impunctate, except for two irregular central rows of tine punctures (sometimes partly obsolete). Elytra separately rounded at base, a trifle broader than prothorax at shoulders, which are roundedly prominent, sides parallel to beyond middle; upper surface depressed, with nine complete fine shallow strix containing regular rows of small distant punctures, which are faint near the suture and become gradually stronger laterally,
the intervals broad, plane, and impunctate; colour shining black. Legs black, shining, impunctate; tarsi ferruginous.

Natal: Malvern.
Type in the Stochholm Museum.
This does not appear to be a common insect, and I have taken it only under the bark of rotten Katir booms (Erythrina caffra).

## 12. Cossonus complanatus, sp. n.

Long. 5, lat. $1 \frac{1}{2} \mathrm{~mm}$.
Head elongate, subquadrate, constricted near base, with very fine scattered punctuation and a minute fovea on forehead; eyes somewhat prominent. Rostrum rather shorter than the head, strongly and quadrangularly dilated from middle to apex, upper surface almost plane and with the punctuation rather stronger and closer than on the head; antennæ ferruginous, inserted close to apex. Prothorax a tritle longer than broad, apex truncate and much narrower than base, which is bisinuate, sides slightly rounded, broadest behind middle, gradually narrowed anteriorly, and with a constriction at apex; upper surface plane, much depressed, with fine scattered punctuation, having an impunctate central line, on each side of which there is near the base a very faint longitudinal impression containing rather deeper punctures, posterior angles with a minute sharp projection; colour black, shining. Elytra strongly depressed, jointly rounded at base, a little broader than prothorax at the shoulders, which are roundedly prominent, sides parallel to far beyond middle; upper surface plane, with ten complete deep striæ containing rows of distinct closely-set punctures, the intervals narrow, plane, and impunctate; colour piceous black, shining. Legs black, bare, finely punctulate: tarsi piceous.

Natal: Malvern.
Type in the British Museum.
I have seen only a single example of this very distinct species, which I captured flying at sundown in August 1897. Its extremely depressed form will at once distinguish it from all other South-African species, its nearest ally in this respect being glabricollis, Boh. These two species are the only ones in which the prothorax is smooth and without any distinct carina or other sculpturing. From glabricollis the present species may be further distinguished by its much shorter and broader rostrum, differently shaped head, and by the deeper and closer striation of the elytra.

## 13. Cossonus immeritus, Fåhr.

Cossonus immeritus, Fåhr. (Efv. Vet.-Ak. Förl. 1871, p. 286.
Long. $4 \frac{3}{5}-5$, lat. $1 \frac{2}{5}-1 \frac{3}{5} \mathrm{~mm}$.
Head shortly conical, impunctate ; forehead with a central fovea; eyes slightly prominent. Rostrum nearly twice as long as head, stout, parallel-sided, slightly curved, punctate on the sides, but glabrous dorsally; antenne stout, ferruginous. Prothorax about as long as broad, apex truncate, much narrower than base, which is bisinuate, sides subparallel from base to beyoud middle, narrowed anteriorly, and with a faint constriction at apex; upper surface slightly convex, with deep subremote punctuation and a median basal impression; the central carina scarcely noticeable, except in the basal impression; colour black, bare, shining. Elytra a little broader than prothorax at the shoulders, which are roundedly prominent, sides parallel to beyond midale; upper surface slightly convex, with ten complete deep and strongly punctured stria, the intervals convex and impunctate; colour black, glabrous. Legs black, impuuctate, tarsi ferruginous.

Caffraria (teste Tiohreus).
T'ype in the Slockholm Museum.

## 14. Cossonus scrobicollis, sp. n.

Long. 4-4 $\frac{1}{2}$, lat. $1_{4}^{3} \mathrm{~mm}$.
Head conical, vertex impunctate; forehead punctulate and with a central fovea; eyes subdepressed. Rostrum longer than head, curved, subeylindrical, and not dilated at apex; punctuation distinct at base, but becoming much finer apically; antenne inserted at middle, short, stout, ferruginous. Prothorax as long as broad, apex truncate and much narrower than base, which is strongly bisinuate, sides but little rounded, slightly constricted behind apex, broadest about middle; upper surface somewhat convex, closely and very coarsely punctured throughont, and with a deep triangular central impression, broadening from apex to base, the impression itself rugosely punctured and containing a complete smooth carina. Elytra separately rounded at base, a little broader than prothorax at shoulders, which are obtusely prominent, sides parallel to beyond middle ; upper surface moderately convex, with ten deep very strongly punctured stria, which are hardly shallower laterally (except the tenth, which is faint), the intervals narrow, subcarinate, and impunctate. Legs piccous, shining, finely punctulate; tarsi ferruginots.

Natal: Verulam; Portuguese E. Africa: Beita (P. A. Sheppard).

Type in the British Museum.
In addition to the characters mentioned in the key, this species may be distinguished from its only near ally, C. immeritus, Fahr., by the following points:-the shorter rostrum; the closer punctuation of the thoras, which is often longitudinally serobiculate; the broader and more deeply punctured striæ on the elytra; and the narrower subcarinate intervals.

This species was found under the bark of rotten Euphorbia trees.

> LIV.-Ten-legged Pycnogonids, with Remarks on the Classification of the Pycnogonida. By Leon J. Cole.

Is a recent paper published in this Journal by T. V. Hodgson (1904), Biologist to the National Antarctic Expedition, appears a description of a most interesting Pycnogonid taken during the stay of the 'Discovery' in winter-quarters in McMurdo Bay. It differs from the ordinary members of the group in possessing five pairs instead of the usual number of four pairs of walking or "ambulatory" legs. In other respects it is very close to the well-known genus Nymphon. Hodgson considers that this remarkable animal should be regarded as representing a new genus as well as a new species, and has proposed for it the name Pentanymphon antarcticum. That it is not a fortuitous or "freak" variation is pretty well shown by the fact that in all twenty-cight individuals were taken, both males and females. They were found inhabiting water from 1.2 to $1: 25$ fathoms in depth.

Hodgson believes that " the presence of a fifth pair of legs [is] a character which separates it from all Pyenogonids hitherto known" ; but as carly as 1837 Eights (i 837 ) published a description of a Pycnogonid with a filth pair of walking-legs from the South Shetland Jslands, and gave to it the name Decolopoda australis-a fact which seems never to have come to the attention of workers on the group since that time. Eights gives a very good description and illustration of the species-much better than the average at that early date,-though the figures do not seem to agree in all details with the description. He states that the entire animal was of a bright scarlet colour, and so figures it; and
regarding their abundance says, "They are to be found in considerable numbers in comnexion with the fuci, thrown up by the waves aiong the shores of the islands, after being detached by the motion of the large masses of ice, from the bottom of the sea." It appears that the specimens were collected by himself, and at least the one from which the description was made is recorded as in the "Cabinet of James Eights." About a year ago I attempted to secure information regarding Dr. James Eights and where he had lived, in the hope of locating these specimens, but was unsuccessful. Thinking they might have been deposited later in the collections of the Boston Society of Natural History, with the assistance of Mr. Johnston, the Curator, I made search there, but with like result.

An interesting question immediately arises as to the relationship of these unusual forms to the other Pyenogonida. It would be natural to expect that they would form a rather closely related and perhaps primitive group-possibly a distinct family--by themsclves; but such does not appear to be the case. As has been stated, the only important feature in which Pentamymphon differs from Nymphon is in the possession of the extra pair of appendages. Decolopoda, on the other hand, resembles more closely in general appearance the genus Chatonymphon of G. O. Sars; but the possession of 10 -jointed palpi throws it out of the family Nymphonidre entirely if we accept the family as limited by Sars ( 1891 , p. 54), though it might be included in the broader definitions given by Meinert (1899, p. 33) and Hoek (1881, p. 17). It still differs, however, from the other known forms in the family by the possession of so many (ten) palpal joints, and would seem to come intermediate between the Nymphonide and the Eurycydidr (Ascorhynchidæ), leaving out of consideration for the present the extra pair of legs. Thre are two ways in which these forms might be related to the other Pycnogonids:-(1) The extra pair of appendages may indicate that they are more primitive and that this is an indication of their origin from a form which possessed a still larger number of segments, thus forming, perhaps, a connexion with the Crustacea; or (2) it may be a character which represents a later differentiation, though this latter does not to me seem at all probable. In this comnexion the speculation of Eights in the paper mentioned above ( 1837, p. 205) is of interest. He says :-"I have placed this interesting animal in the class ARACHNIDES, in consequence of its close approximation to

Latreille's second family Pycnogonides *, of his order Trachearle; it possesses all of the characters, besides which it has a segment supporting two additional legs, making in all five perfect pairs; this latter circumstance would doubtless bring it in the preceding class CRUSTACEA, being a character which strikingly distinguishes the animals that compose it ; at all events, I think it will certainly form a connectinglink in the great chain of the animal kingdom, between these two classes, passing from the CRUSTACEA into the ARACHNIDES by the genera Nymphon, Phoxichili, Pycnogonum, \&c."

That the Pyenogonids form a remarkably homogencous group has often been mentioned, and with the discovery of new forms the existing gaps are rapidly being filled. It is the existence of gaps in our series that enables us to designate species, gencra, families, and other taxonomic groups, and as these gaps become gradually filled the demarcation of the groups becomes incucasingly difficult. It leads at first either to putting narrower limits upon our various terms and splitting one genus into a number of genera, one species into a number of species, \&c., or the formation of new subgroups as new subgenera, subspecies, \&c. Both of these processes have been going on extensively in nearly all branches of the animal kingdom; but as the series becomes more and more complete it becomes more and more difficult to draw lines of distinction-in other words, to find gaps; and as any gap becomes filled our subspecies, species, or genus, or whatever it is, must expand to include all those forms to the next existing break in the series, or else an arbitrary artificial demarcation must be made. In the Pycnogonida the series of characters upon which the present classification depends is so nearly complete-the differences are so small-that the limitations, especially of the larger groups, such as the families, are admittedly arbitrary, and it is a matter upon which hardly two authors agree. But whereas this profusion of "connecting-links" is a source of much confusion to the taxonomist, it should enable us to trace very definitely the phylogenetic development. Whether this can be done on the basis of the characters at present in use we cannot say until a more careful examination has been made of the anatomical details of other organs, and probably not until the early embryonic and larval development of more of the species is better known, though I believe a thorough

[^48]
knowledge of the embryology is going to be of more importance in elucidating the question of the relationship of the Pyenogonida to the other Arthropoda.

In the following discussion I have used the families as adopted by Sars (1891), not because I consider them necessarily more true to a correct system than those given by some other authors, but because they are better adapted to my present purpose. I shall use them simply as milestones to mark certain points, or, perhaps better, stretches along the road of phylogenetic development, without intending to imply that these stretches might not consistently be fewer or greater in number, and with their limits at different points.

The systems given by most recent authors differ from that which I have temporarily adopted here for the most part only in the employment of different names, derived from other genera, or in being more or less inclusive. The number of families given by Sars (1891, p. 144) is larger than is generally recognized, and consequently his classification is more useful to me in showing the gradual stages of differentiation ; and where, in one or two instances, this series has not been complete enough for my purpose, I have introduced generic names for greater completeness. In most cases the names of the families are derived from well-known genera; where another genus in the family is perhaps better known I have indicated the fact. I have retained the order of sequence as given by Sars, except for the transposition of the Pasithoidæ to a position next the Ammotheidæ instead of the Eurycydidæ, as they appear to be more nearly related to the former.

The character on which the families are chiefly based is the presence or absence or the state of deveiopment attained by the first three pairs of appendages-chelifori, palpi, and ovigera. In general those forms which possess these appendages well developed are to be considered the more primitive, a fact shown by the ontogenetic development of those which do not possess them in the fully adult stage. The condition of these appendages (together with the presence or absence of denticulate spines on the ovigera, the degree of trunk-segmentation, and the number and position of the genital openings) is given for the varions families in the table on p. 408 .

It will be noticed from the table that there are two diverging scries, each starting from a primitive condition, fairly well represented, seemingly, by Decolopoda. Decolopoda might well be the basis for a distinct family, the Decolopodidæ, if it were not for difficulties encountered in Ann. \& Mag. N. Hist. Ser. 7. Jol. xv.

## PYCNOGONOMORPHA.

Pycnogonidæ.

Phoxichilidso.

In the table I have indicated the division of the families into orders as arranged by Sars. Lankester (1904) makes practically the same grouping, but employs different names. I can see no valid reason for a division into Achelata and Euchelata (or into Pyenogonomorpha and Nymphonomorpha, as given by Lankester), a distinction based on the absence of a single pair of organs (the chelifori) in the former group, since the palpi are absent or rudimentary in the Pallenidx, and in the Phoxichilidiidæ the ovigera are present only in the male. A reference to the table will show that there is no place in this series where a line can be drawn based on a number of characters-in fact, not more than a single one of the characters given changes at any given point in the series. It therefore seems best to make but two orders, representing the two divergent series. These can well be designated by
names derived from their most specialized forms; for one I have therefore used the name Pycnogonomorpha, Pocock, given by Lankester ( $\mathbf{1 9} \mathbf{2} 4, \mathrm{p} .225$ ), while for the sake of consistency I have proposed the term Colossendcomorpha for the other order.

In Decolopoda, of all known Pyenogonids, we have the most primitive conditions. Here the chelifori are well developed and strongly chelate, the palpi are present and made up of ten joints, the ovigera are present in both sexes * and are provided with denticulate spines, and the trunksegmentation is distinct. In the Pycnogonomorpha we find that there is a gradual tendency to a reduction of the anterior appendages: the chelifori are lost in the Phoxichilide; in the palpi the joints are reduced one half in number at tha begiming, and are lost entirely in some of the Pallenidæ; the females no longer bear ovigera in the Puoxichilidide, and in Hannonia the denticulate spines are lacking from these appendages; the segmentation remains distinct and well marked throughout. In the Colossendcomorpha the chelifori have rather rudimentary chelæ in the Eurycydidæ, are present (usually) but not chelate in adult Ammotheidre, and are lost entirely in the Pasithoidx; the palpi remain well developed throughout, but are reduced as to tae number of joints composing thern in the Ammotheidie, in which character they make a slight break in the gradation of the series $\dagger$; the ovigera are retained in both sexes thronghout, though the denticulate spines are lost in the Pasithoidie; the trunk-segmentation shows a direct gradation from a well-marked condition in the Eurycydidæ to a complete coalition in the Pasithoidie, both conditions being found in the intermediate family.

The most remarkable features in these two scrics are the directness of the two lines of differentiation and the similar tendency in both to a reduction of the parts. Each of the families is intermediate, in the characters commonly used for their distinction, between the one that precedes and the one that follows (with the minor exception in the case of the Ammotheidæ, as noted). This approaches the kind of "chain" that was looked for by some of the early evolu-

[^49]tionists, and I know of no other group where it is so direct and complete. The genera within the families will undoubtedly show much secondary branching from this direct line of descent.

White it is difficult to understand why so many characters should vary in common if such were the case, still it is possible that the utilization of these characters dues not give us a true clansification. This is suggested by the positions of the genital openings, as shown in the above table, as well as by the structure of the ovaries and possibly some of the other organs. The condition of the ovary in Nymphon has led Hoek (188i, p. 131) to remark:-" I perfectly believe, however, that the occurrence of a part of the ovary in the body of a Pyenogonid is rather rare, because, as a rule, only the lateral excrescences remain. No doubt this must be considered as a secondary condition; and seeing that, so far as I could ascertain, it is the rule in all the species of Nymphon, my original opinion, that the genus Nymphon, of all the genera of Pyenogonida, resembled most the hypothetical ancestors of our group, was severely shaken."

The system here brought out differs in many respects from that of Hoek (1881 a , p. 495), but it is interesting to note how closely the form Decolopoda agrees with his hypothetical genus Archipycnoyonum, which he postulates as follows (l. c. p. 491):-"Archipycnogonum (genre hypothétique).Pyenogonides de grandes dimensions, aux mandibules fortes de trois articles et armées d'une pince terminale, aux palpes longues de dix articles, aux pattes orifères, également de dix articles, dont les quatre derniers sont pourvus de plusieurs rangées d'épines en forme de feuilles. Les pattes thoracique ont huit articles et se terminent par une griffe accompagnée de deux griffes accessoires." Eights's deseription of Decolopoda agrees in all particulars with this except that he does not mention the "accessory claws," which, however, it is fair to assume were present. Hodgson mentions and figures them in Pentanymphon. Had Hoek but been aware of it there was 110 need for him to construct a hypothetical genus as the starting-point of the Pyenogonids-it had already been described just as he wanted it (except that it had one more pair of legs than he supposed) more than forty years earlier.

Pentanymphon I have placed between Decolopoda and the Nymphonide ; but Boreonymphon and Chetomymphon, with their compact bodies and closely approximated lateral processes, would much more nearly resemble Decolopoda in gencral appearance if they had but the fifth pair of legs. It would be expected that such a character as the possession
of an extra segment bearing a pair of legs would be more than sufficient for the establishment of a separate family in a group where family distinctions are based upon such minor characters as the extent of development or suppression of certainappendages, with no question of the loss of a segment ; but Pentanymphon apparently resembles Nymphon so closely in all its minor details, even to the presence of a claw, denticulate on one border, terminating the oviger, that it is incomprehensible that these characters could have been developed independently. Exeept for the extra legs Pentanymphon is in all respects a true Nymphon, and this, did we not know of another ten legged form, would lead us to suppose that it represented the primitive stem of the Pyenogonida. Must we, then, conclude that the group has had two points of origin?

Hodgson (1904, p. 462) states that he understands Mr. W. S. Bruce, of the Scottish Antarctic Expedition, has taken several specimens of a ten-legged Pyenogonid from the Wedtell Sea which may prove to be identical with Pentamymphon antarcticum. But since the Weddell Sea is on the opposite side of the Antarctic continent to McMurdo Bay, and not far from the South Shetland Islands, it would not be surprising if Mr. Bruce's specimens turned out to be identical with Derolopoda australis *. Should they prove to be Derolopoda rediseovered, a careful study of them may add much of importance to our knowledge of the Pyenogonida. lt is noteworthy that the two species of ten-legged Pyenogonids so far described both come from the Antaretic, though from opposite sides of the Polar areat.

The bearing of this extra appendiculate segment on the ancestry of the Pyenogonida and their relationship to the other Arthropods I shall not discuss at this time, except to call attention to the fact that it adds further difficulties to

* [Mr. C. V. Hodoson has kindly sent us the following note on this point:-Mr. W. S. Bruce's collection of Pyenogonida from the South Orkneys includes a single specimen of Pentanymphon antarcticum and several specimens of Eights's Decalopoda austratis. 'Ihis latter has been fully described in a paper communicated to the Royal Physical Society of Edinburgh on Jan. 23, 1905. With regard to the genital apertures, they exist in both sexes of Decalopoda australis on the second coxia of all the legs. In Pentanymphon antarcticum they are very difticult to observe, and at present I can only vouch for the female. They occur on all the segments also.-EDs. $]$
$\dagger$ South Shetlaud Islands, about lat. $63^{\circ}$ S., long. $60^{\circ} \mathrm{W} . ;$ McMEurdo Bay, approximately lat. $78^{\circ} \mathrm{S}$, long. $168^{\circ} \mathrm{E}$. (From map showing work of National Antarctic Expedition, 'Geographical Journal,' vol. xxis. no. 2, August 1904.)
the acceptance of the homologies of the metameres and appendages of the Pycnogonida as suggested by Lankester (1904), who believes that the whole portion of these animals anterior to the so-called abdomen corresponds to the prosoma of the Arachnids. The segment which bears the fourth pair of walking-legs he thinks represents the pregenital somite, and it is true that wherever else the genital openings may be wanting, they appear always to be present on this pair of legs. Neither Eights nor Hodgson mentions the genital openings in the ten-legred forms, and a knowledge of conditions there will be of considerable theoretical interest. It may be mentioned here that Lankester appears to have overlooked the two pairs of appendages present in the embryos of all Pycnogonids (possibly absent in Pallene and related species: Mcinert, 1899), which are not represented in the appendages of any adult species. Lankester considers the Pyenogonida a subclass of the Arachnida, and Meinert, chiefly from his studies of the embryology, also relates them to that group, but differs entirely from Lankester in his conception of the homologies of the various appendages. Carpenter (1903) likewise classes them with the Arachnida and agrees more nearly with Lankester as to the homologies of the metameres; he believes, however, that the palps of the Pyenogonids are not represented by appendages in living Arachinids, and concludes that the present type of Arachnid head "was preceded by a head with four pairs" of appendages. More recently Meisenheimer (1902) has male a careful study of the carly embryonic stages of Ammothea echinatt, and has reached conclusions exactly opposed to those of Meinert. In a short paper giving his main results Meisenheimer (1902A), after presenting his evidence, concludes (p.64):-"Und somit hat uns die Larvenentwicklung der Pantopoden mit grosser Bestimmtheit auf eine nahe Verwandtschaft dieser Gruppe mit den Crustacean hingeführt." It is thus obvious that naturalists are no nearer to agreeing to-day upon the systematic position of the Pycnogonida than they have been at any time in the past.

LV.-Descriptions of new Species of Sphegidæ and Cero. palidæ from the Khasia Hills, Assam. By P. Cameron.
[Continued from p. 229.]

## Ceropalidæ.

Ceropales pruinosa, sp. n .
Black, the scape of the antennæ broadly below, palpi, a narrow interrupted line on the pronotum, the apical half of
the antenual keel above, the inner orbits from the incision to the base of the mandibles, the outer orbits much more narrowly and the apex of the clypeus more broadly, especially on the sides, lemon-yellow. Legs black, thickly covered with a silvery pile, especially thick on the coxe, where it has a golden hue; the calcaria and a mark on the upper side of the base of the hind tibiæ yellowish white; claws rufous. Wings hyaline, the apex from the base of the radial cellule slightly but distinctly infuscated, the apical nervures fuscous; the apical abscissa of radius obliquely turned upwards; the second cubital cellule at the top is twice the length of the third; both the recurrent nervures are received near the base of the apical third of the cellules; the accessory nervure in hind wings interstitial. if.

Length 11 mm .
Shining; the front and vertex sparsely covered with long hair ; the face and clypeus with depressed silvery pubescence. Below the ocelli is a longish furrow, deep in the middle, widest at the base. Antennal keel stout, obliquely narrowed at the base and apex. Mandibular teeth ferruginous. Proand mesothorax covered with depressed silvery pubescence; the metanotum, especially at the apex, with long woolly hair. The scutellum and metanotum more distinctly punctured than the mesonotum. Abdomen covered with silky pubescence.

The Khasia species of Pseudagenia may be grouped as follows:-
A. Body for the greater part fulcous.
a. Thorax fulvous.

Wings yellow, the apex violaceous ...... languida.
Wings fuscous hyaline or hyaline........ excellens, pulchrifrons, lyrata, nigritibius. agitata.
B. Body for the greater part black; the legs more or less red; the wings hyaline or more or less fuscous. $\qquad$
C. Body black; the hind femora red; the wings hyaline, with a fuscous fascia
flavicollis, nigripalpis, arethusa, lacteijennis.
gnema.
D. Body black; the thorax red; the wings hyaline, with one or more fascire
himalayensis and agenia, Sm.
E. Body black or purple; hind femora red .... prophetica, purpurea.

Pseudagenia languida, sp. n.
Ferruginous, the head, thorax, apical five joints of the antennæ, and the basal three segments of the abdomen at
the base black. Wings bright yellowish hyaline, the apex from shortly behind the second transverse cubital nervure fuscous-violaceous. Ilead and thorax densely covered with golden pubescence. $ㅇ$.

Length 16 mm .
Eyes slightly converging above. Apex of clypeus rounded in the middle, the sides roundly curved. Mandibular teeth black. Legs uniformly ferruginous, except the apices of the four basal tarsal joints and the apical one entirely. Second cubital cellule scarcely shorter than the third; the first recurrent nervure is received shortly, but distinctly, in front of the basal third, the second very shortly behind the middle of the cellule.

## Pseudagenia pulchrifrons, sp. n.

In Bingham's key on p. 107 this species would fit into "A. Wings yellowish, apex infuscated" and into a new section " $c$. Head, thorax, and abdomen ferruginous, the head thickly covered with bright golden pile."

Ferruginous, the mesosternum, the apical five antennal joints above and at the sides, the base of the first abdominal segment, base and apex of the second in the middle and the base of the third broadly, black. Wings hyaline, with a smoky fulvous tinge, the apical half slightly darker than the basal; the second cubital cellule slightly but distinctly longer than the third; the first recurrent nervure received shortly beyond the middle, the second in the basal third. Leg* fulvous; the fore coxre at the base behind, the middle broadly black behind, the posterior with a large mark at the base below, the base and apex of the second joint of the hind tarsi, the third joint above and the apical two entirely, black. of.

Length 14 mm .
Mandibles rufous, yellowish at the bas?, the tips black. Palpi rufous, paler at the base. Front thickly and the face and clypeus covered with golden pubescence and sparsely with long fuscous hair. Apical half of clypeus black; the middle broadly depressed. Median segment with a gradually rounded slope to the apex ; faintly transversely striat d, thickly covered with long fuscous hair and with no longitudinal furrow. Pleuræ smooth and shiaing, sparsely covered with long fuscous hair. Apical segments of the abdomen covered with fulvous pubescence and sparsely with long blackish hair ; the abdomen is fully longer than the thorax. The sides and apex of the mesonotum are narrowly black.

Comes near to $P$. deceptrix, Bing., which is different apparently from $P$. deceptor, Sm., a Malay species. Smith's species is certainly different from the one I have described above.

## Pseudagenia lyrata, sp. n.

Fulvous, the face, oral region, and inner orbits clear yellow; over the antenne is a black transverse mark, broader than long; the ocellar region black, and on the occiput is a large black mark, uniting the eyes above and obliquely narrowed on the lower side; a line on the mesonotum at the tegulæ, a small mark on the pleure immediately beneath them, a larger mark on the base of the mesopleure over the coxr, the base of the mesosternum, a somewhat triangular mark on the base of the median segment, and the lower half of the base of the metapleuræ, black. Legs fulvous, the anterior pair with a more yellowish hue in frout; hinder tarsi black, the calcaria dark fuscous. Abdomen with the second segment with a narrow, the third to sixth with broader transverse black bands. $\delta$.

Length 10 mm .
The scape and basal joints of the flagellum fulvous, the middle joints black above, the apical eutirely black. The mesonotum is of a darker tint than the pronotum and is minutely closely punctured. The median segment has an oblique, somewhat rounded slope and is closely transversely striated. The second cubital cellule, b fore and behind, is a little shorter than the third; the first recurrent nervure is received very shortly behind the middle, the second in the basal third of the cellule.

## Pseudagenia nigritibiis, sp. n.

Fulvous; the head below the antennæ densely covered with bright golden pubescence, the mandibles and palpi pallid yellow; the keel along the sides of the mesonotum, a band at the base of the median segment, the meso- and metasternum, the base of the first abdominal segment, the base of the second narrowly, its apex more widely, and the greater part of the third, fourth, and fifth segments, above and beneath, black. Wings hyaline, iridescent, the stigma dark fuscous; the second and third cubital cellules equal in length in front; the first recurrent nervure received near the basal third, the second nearer the base of the cellule. $\delta^{\pi}$.

Length 10 mm .
Mandibles and palpi pallid yellow, the vertex sparsely covered
with longish black hair ; the hind ocelli separated from each other by a less distance than they are from the eyes, which hardly converge below. Metanotum strongly transversely striated and sparsely corered with longish fuscous hair.

Closely related to P. lyrata, but may be separated from it by its larger size, black hind tibir, black vertex and front, by the first recurrent nervure not being received in the middle of the cellule, and by the apex of the abdomen being more widely and distinctly black.

## Pseudagenia agitata, sp. n.

Black; the head and thorax densely covered with golden pubescence; the antennal scape reddish, the basal six joints of the flagellum brownish bencath ; the clypeus, labrum, mandibles, and palpi yellow; the prothorax pale ycllow; abdomen fulvous, the first segment black, the black mark becoming narrowed towards the apex, and the four apical segments broadly black. Jeegs rufo-fulvous; the fore coxæ pale yellow, the four posterior black at the base behind and covered with golden pile; the four hind trochanters black. Wings hyaline, the basal half with a faint fulvous tint; the apex with a narrow, faint, smoky cloud. ठ.

## Length 12 mm .

Apex of clypeus slightly incised; the labrum slightly and broadly incised and fringed with golden hair. Mandibles covered with golden pile. Eyes slightly, but distinctly, converging below; the hind ocelli separated from the eyes by a distinctly greater distance than they are from each other. The second and third cubital cellules equal in length ; the first recurent nervure is received very shortly besond, the second in, the basal third. The penultinate ventral segment is roundly incised in the middle; its apex at the sides bears a tooth which becomes gradually enlarged from the base to the apex, which is curved and hook-shaped at the top.

Comes near to $P$. pulchrifions, from which it may be known by the greater part of the flagellum being black; the ground-colour of the thorax is black; the base of the petiole and the apical segments of the abdomen black.

## Pseudagenia flavicollis, sp. n.

Length 17 mm . $\quad$.
Comes best into Bingham's section "F. Wings hyaline, the apex fuscous," but is very different from anything included in it ; it agrees, apart from the wings, with group A.

Thorax black, thickly corered with golden pubescence ; the
prothorax (except a black line above the middle), an irregular crown-shaped mark in the middle of the mesonotum near the apex, the scutellum (except at the apex), postscutellum, a large triangular oblique mark under the hind wings, one, longer than broad, behind the spiracles, and a square mark in the centre of the apex of the metanotum, pallid yellow. Legs rufous; the fore coxa pallid yellow, the four hinder black marked with yellow behind ; the fore trochanters black, palid yellow in the middle, the four hinder black; the anterior femora, tibie, and tarsi pallid rufous; the base of the femora yellowish; the hind femora rufous, black at the base; the f.ur hinder tibix and tarsi blackish; the middle tibie rufous, the hinder yellowish at the base; the calcaria yellowish; the tibial spines and claws rufous. The uings have a slight, but distinct, yellowish tint; the apex beyond the third transverse cubital nervure infuscated; at the top the third cubital cellule is shorter than the second; the first recurrent neryure is received shortly beyond the 1 iddle, the second at the apex of the basal third of the cellule. Abdomen black, covered with golden pile; on the second segment is a large pallid yellow mark, narrowed in the centre at the apex, its sides dilated, the middle at the apex triangularly incised.

Head thickly covered with depressed golden pile, which lides the texture. Hind ocelli separated from each other by a less distance than they are from the eyes, which are parallel. Apex of clypeus transverse; the labrum black, thickly covered with fulvous hair. Mandibles yellow, thickly covered with golden pile; the teeth black. Palpi bare, fulvous. Antemal scape fulvous; the flagellum of a dulker reddish-fulvous colour, black above. Scutcllum sparsely covered with short hair; the postscutellum more thickly with longer pale fuscous hair. Median segment opaque, obscurely transversely striated.

## Pseudagenia nigripalpis, sp. n.

Length 10 mm . $\mathrm{o}^{7}$.
Belongs to Bingham's section "C. Wings clear hyaline," and " $b^{2}$. Abdomen black, posterior margins of the segments narrowly white," which will now stand :-
The middle femora red, the palpi white ................. albilabris.
The middle femora black; the papipi black............... . nigripalyis.
black; the antemal scape below, the sides broadly, and the apex narrowly of the clypeus, labrum, the lower eyeorbits (broadly below, narrowly above), and the middle of the
mandibles, yellowish white. Legs black; the hinder femora (except at the base and apex) red ; the four anterior coxa, the fore femora broadly and the middle at the apex, all in front, yellowish white and thickly covered with silvery pile. Wings hyaline, with a distinct steely tinge ; the stigma and nervures black; the second cubital cellule slightly shorter than the third before and behind ; the first recurrent nervure received in the middle, the second near the baval third of the cellule. Abdomen black, the segments with a narrow band of yellow at the apex; the first also broadly on the sides behind and the last broadly on the sides white. $\delta$.

Lower part of front, face, and clypeus thickly covered with silvery pubescence; the vertex sparsely with longish black hair. Apex of clypeus transrerse, the sides oblique. Median segment with a gradually rounded slope from the base to the apex, finely transversely striated ; the strix stronger towards the apes. Hypopygium broadly obliquely furrowed down the sides; the petiole becomes gradually distinctly widened towards the apex.
P. arethusa, Cam., is related to the present species; it may be known from it by the four front legs being reddish, by the head being entirely black in front, by the less clear wings, testaccous palpi, and non-striated metanotum.

## Pseudagenia lacteipennis, sp. n.

Length 8 mm . ${ }^{\text {or }}$.
In Bingham's table, p. 108, this species would enter into "D. Wings clear hyaline, or hyaline with a yellowish tint, with oue fuscous subapical fascia," and " $b$. Median segment not furrowed down the middle," which will nuw be subdivided :-
Wings hyaline, the fuscous cloud occupying the base of the radial cellule; abdomen black
lavicula, Bing.
Wings lacteous, not clear hyaline, the cloud occupying
the base of the radial cellule; the sides of the petiole and the base of the second segment yellowish white .............................. lacteipennis.

Antennal scape black. Black; the sides of the first abdominal segment dark, the base and sides of the second and the apical segment palc, testaceous. Legs black; the apex of the fore femora below, the anterior tibice and tarsi, and the middle tibiæ (except a broad band at the base and a narrow one at the apex) rufo-testaceous; the hind femora broadly rufous below and the calcaria dark testaceous. Wings hyaline, with a milky tinge ; below the stigma, at the
base of the radial cellule and in the second and third cuhital cellules, is a pale brownish smoky cloud; the second and third cubital cellules in front are equal in length; behind, the second is distinctly shorter than the third.

Vertex and front fincly and closely punctured; the face and clypeus thickly covered with silvery pubescence. Pronotum fincly and closely transversely striated. Nesonotum closely punctured; the scutellum more coarsely punctured. Meso- and metapleure granular, covered thickly with white hair.

## Pseudagenia purpurea, sp. n.

Purple; the thorax mixed with llue and micaccons shades; the coxæ blue, the rest of the legs black, except the hinder femora, which are red, with the base and apex narrowly black. Wings hyaline, the apical nervures fuscous, the cubital cellules about equal in length; the first recurrent nerrure received near the middle, the second at the apex of the basal third of the cellule. +

Length 12 mm .
Antennæ brownish, the scape black. Head closely punctured; the face and clypeus thickly covered with silvery pubescence, the front and vertex sparsely with fuscous. Mandibles thickly covered with silvery pubescence, the tecth dark rufous, the palpi dark fuscous. Hind ocelli separated from the eyes by double the distance they are from each other. Pronotum strongly, but not decply or closely, punctured; the mesonotum much more closely punctured; on it, opposite the tegulæ, is a narrow shallow furrow; the scutellum is more closely and fincly punctured and finely striated down the middle. Metanotum rather strongly and closely transversely striated, the striee stronger towards the apex; down the middle is a shallow, but distinct, furrow. Pleuræ closely, but not strongly, punctured; on the propleure, in the middle, is a wide shallow V -shaped furrow; the metapleure below the forea more fincly and closely punctured than the rest. Abdomen pruinose, thickly so at the apex ; smooth and shining; the pygidium very smooth, shining, and glabrous.

## Pseudagenia prophetica, sp. n.

Blue; the antennæ, mandibles, palpi, and legs black; the mandibles obscure rufous at the apex; the coxe with a distinct blue tint ; the hind femora red, black at the base and apex. Wings clear hyaline, the nervures and stigma black. $\quad$.

Length $10-11 \mathrm{~mm}$.
Antenne black, the scape covered with pale pubescence; the third joint about one third longer than the fourth. Ifead closely punctured; below the antennæ thickly covered with silvery pubescence; there is a shallow furrow on the lower part of the front. Eyes curved on the inner side, not converging. Pronotum bearing shallow punctures (except on the apex, which is depressed). Mesonotum with scutellum closely punctured. Median segment coarsely transversely striated ; the base with a shallow furrow in the middle. Mesopleuræ closely punctured ; the punctures on the lower part of the metapleuræ run into striations. The second cubital cellule in front is slightly, but distinctly, shorter than the third ; the first recurrent is received in the middle, the second at the basal third of the cellule. Tegulæ deep black.

Comes near to $P$. blanda; it may be known from that species by the head and thorax being closely and distinctly, rather strongly, punctured all over; the metanotum in particular is much more coarsely and irregularly transversely striated; it is more pubescent and not so thickly covered with white pile; the alar nervures and stigma are black. not piceous; and the propleuræ are more distinctly hollowed.

## Pseudagenia himalayensis, sp. n.

Length 8 mm . ${ }^{0}$.
In Bingham's table, p. 108, this species is to be included in "E. Wings clear hyaline, or hyaline with a yellow timge, with two fuscous fasciæ on the fore wings," and " $b$. Thorax red," which will now be divided :-
Anterior margin of clrpeus toothed in the middle; abdomen and legs entively black ..................
Anterior margin of clypeus not toothed; the base of the petiole and of the second abdominal segment testaceous; the four anterior tibir and the front tarsi pale testace
xgina.
himalayensis.

Head black; the face, cheeks, and clypeus thickly covered with silvery pubescence; the cheeks (the mark becoming wider towards the apex), the sides of the clypeus broadly and the sides of the apex, the middle of the mandibles, and the palpi, yellowish. Thorax rufous, the base and middle of the apex of mesosternum black; the pleure and breast thickly covered with silvery pubescence; the pro- and mesonotum closely punctured, somewhat opaque; the median segment opaque, its apex closely transversely striated, the base black and depressed in the middle. Legs black; the apex of fore
femora, tibiæ and tarsi, and the middle tibix (except at the apex) testaccous. Wings clear hyaline, the costa and nervures black; the stigma fuscous in the middle, a faint fuscous cloud occupies the basal three fourths and the whole of the second and third cubital cellules; the first recurrent nervure is received very shortly before the middle, the second in the basal fourth. Abdomen pruinose, the base and sides of the petiole rufo-, the base of the second segment yellowish, testaceous; the sides of the basal and the whole of the second ventral segments yellowish testaceous.
[To be continued.]

## geological society.

December 21st, 1904.—J. E. Marr, Sc.D., F.R.S., President, in the Chair.

The following communication was read:-
' On Certain Genera and Species of Lytoceratidæ.' By S. S. Buckman, F.G.S.
This paper deals with certain specimens sent by Mr. Beeby Thompson from the Northampton Sands, one of which is remarkable for its homœomorphy with Phylloceras. In order to classify the series of Toarcian-Aalenian Lytoceratide to which these species belong (jurense and allied groups), it is necessary to note that there is evidence of a definite sequence of phylogenetic stages. In ornament there is, at first, elaboration ; but, later, simplification from a costate to a smooth stage. In whorl-shape there is a tendency to pass from the primitive evolute to the involute whorl, the umbilicus constantly contracting. Parallel with this there is a further tendency to pass from stout to more compressed whorls. While the Lytoceratidæ have a more primitive whorl-shape than the Phylloceratidæ, their lobe-line is more adranced ; and hence, while the advance of the former produces a certain external homoomorphy with the latter, the more advanced lobe-line remains a feature of distinction. The successive stages of development may be indicated in terms of species, thus: (1) Germaini, (2) torulosum, (3) annulose species not yet named, (4) jurense, and (5) phylloceratoidan. Four new gencra are described, and two new species; three new names are proposed, and one generic name revised.

[SEVENTH SERIES.]

No. 89. MAY 1905.
LVI.-Descriptions of new Genera and Species of Syntomidæ, Arctiadæ, Agaristidæ, and Noctuidæ. By Sir Georae F. Hampson, Bart., F.Z.S.
The following genera and species form a third supplement to the first five volumes of the 'Catalogue of Lepidoptera Phalænæ in the British Museum '-the first paper on the subject in the Ann. \& Mag. Nat. Hist. ser. 7, vol. viii. pp. 165-186 (1901), and the second in the same series, vol. xi. pp. 337-351 (1903), -and the numbers before the species indicate the position of the species in the classification adopted in those volumes. The types are in the British Museum.

## Syntomidæ. (Vol. I.)

## Page 53. Genus Symphlebomis, nov.

Type, S. antipolo, Semp. Schmett. Phil. ii. p. 418, pl. liii. fig. 2 (1898).
Proboscis fully developed; palpi porrect, not reaching beyond the frons; antennæ of male ciliated. Fore wing of female with vein 3 from angle of cell; 4, 5 strongly stalked; 6 from well below upper angle; 7, 8, and 11 stalked ; 9, 10 absent: male with a fold below base of cell; vein 1 sinuous, 2 bent upwards near its base; the lower angle of cell bent up to upper angle, with the opening of a very large pouch above it. Hind wing with veins 3 and 5 from angle of cell, 4 absent, 6, 7 coincident.
Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.

## Page 114. Genus Neëressa, nov.

Type, N. sagada, Semp. Schmett. Phil. ii. p. 423 (1898).
Proboscis fully developed; palpi porrect, not reaching beyond the frons; antenna of female simple; hind tibix with the medial spurs absent. Fore wing long and narrow; veins 3, 5 shortly stalked, 4 absent; 6 from well below upper angle; 7, 8, and 11 stalked; 9, 10 absent. Hind wing with vein 3 from angle of cell, 4 absent, 5 from well above angle; 6, 7 coincident.

## 288 a. Metarctia hematricha, sp.n.

ठ. Fuscous brown; head, thorax, and abdomen clothed chiefly with blood-red hair. Fore wing with some blood-red hair at base. Hind wing with the inner area tinged with blood-red.

Hab. Abyssinia, Kutai Metha (Degen), 1 ot type. Exp. 44 mm .

## 298 a. Pseudapiconoma meloena, sp. n.

ㅇ. Head and thorax deep olive-brown; abdomen deep olive-brown, dorsally suffused with green except first two segments, the lateral tufts orange at tips. Fore wing deep olive-brown ; a triangular hyaline spot in end of cell; an oblique curved spot below base of vein 2 , with a round spot below it and an elongate spot above inner margin, with its upper edge indented; a wedge-shaped spot above vein 7, a small triangular spot above base of vein 6 and a quadrate spot above its middle, a large quadrate spot above vein 5 , an elongate spot above 4, quadrate spot above 3, very large elongate patch above 2, and quadrate patch above 1. Hind wing deep olive-brown, the cell and inner area thinly scaled; a small hyaline spot above vein 5 and small elongate spots from below 5 to before 2 .

Hab. UgandA, Masaka (Chisty), 1 \& type. Exp. 54 mm .

## 312 a. Sphecosoma metamela, sp. n.

ठ. Head and thorax yellow ; antenner and vertex of head black; tegulæ black at extremity; patagia edged with black; thorax with dorsal black stripe ; abdomen fulvous, with two fine black streaks on first segment, and the three terminal segments black. Fore wing jellowish hyaline, the costal half slightly clouded with fulvous, the veins blackish ;
fine fulvous streaks below costa and above inner margin. Hind wing yellowish hyaline, the veins blackish.

Hab. Paraguay, Sapucay (Foster), 1 ot type. Eup. 24 mm .

## 354 a. Isanthrene fulvipuncta, sp. n.

Isanthrene varia, Hmpsn. Cat. Lep. Phal. i. p. 176 (part.).
Head, thorax, and abdomen black-brown ; antennæ fulvous, the shaft ringed with black and the branches partly black; frons, vertex of head, and tegulæ with silvery-blue patches; patagia with obscure fulvous streaks; fore cosæ with blue patches, hind coxæ with orange spots, the base of femora with streak above tarsi and extremity of hind tibix orange; abdomen with two orange dorsal points on first segment, followed by paired fulvous spots on the next two segments, subdorsal white points and yellow lateral spots on second segment, the other segments with leaden subdorsal fascie with blue spots on them, the ventral surface with white band at base, followed by sublateral white spots on next segment and blue spots on third segment. Fore wing hyaline, the costal half tinged with yellow ; the veins brown and fulvous; two silvery-blue points at base; a fulvous streak, subcostal towards base, then becoming costal; the inner area dark, with fulvous streaks above and below vein 1 on basal half; a terminal dark band with slightly irregular inner edge, expanding somewhat towards apex and angled inwards at vein 2. Hind wing hyaline, the veins dark, a narrow terminal band slightly incurved at veins 2 and 1; the underside with the cell and costal area except costal edge fulvous.

Hab. Panama, Chiriqui (Champion), 1 i type, GodmanSalvin Coll. Exp. 42 mm .

Page 179. For Bombiliodes read Aurochloris, Hïbn. Verz. p. 125 (1827), which has precedence. Type almon, which will come next enagrus.
386. Giymnelia pitthea.-Dr. Staudinger has Erom two different collectors received specimens taken in copulâ with 940. Pseudosphenoptera basalis, and it seems probable that it is the male of that species, in which case pitthece and cocko should be removed to Pseudosphenoptera; the hind witig is so minute in the male that the neuration is not quite certain, and the specimens of basalis are all females.

## 429 a. Loxophlebia cinctata, sp. n.

ㅇ. Head black ; palpi in front, basal joint of antennæ in front, and gulæ yellow ; frons white; thorax yellow, the patagia black except upper edge, a broad dorsal black stripe; abdomen yellow, a dorsal black stripe, the second and third segments with dorsal black bands, the three terminal segments blue-black. Fore wing hyaline, the veins and margins black; the base yellow, a yellow streak below costa to well beyond middle; veins $6,5,4$ yellow from cell to the terminal black band, which expands widely on apical area and slightly below vein 2; a black discoidal bar. Hind wing hyaline, the base yellow ; the cell with black spot in extremity; the veins yellow from cell to the terminal black band, which expands on apical area and on inner margin to near base.

Hab. Venezuela, Caura Valley (Klages), 2 \& type. Exp. 28 mm .
599. Saurita attenuata, n. n.,
tenuis being preoccupied, $\nabla$. no. 613.

## 637 a. Eurota xanthosoma, sp. n.

$\delta$. Head and thorax black-brown, the vertex of head, tegulæ, shoulders, and patches on fore coxæ and pectus orange-yellow; abdomen orange, the anal tuft black below. Fore wing black, the basal area orange-yellow; a semihyaline white patch in terminal half of cell and a quadrate patch below it; an irregular postmedial series of semihyaline spots between veins 7 and 2, those above veins 4, 3 extending to near termen, and the one above vein 2 minute. Hind wing black, the base irregularly orange; a semihyaline white patch beyond the cell between veins 7 and 2 .

Hab. Argentina, Gran Chaco, near Florenzia (S. R. Wagner), 1 ठ type. Exp. 30 mm .

Page 326. For Mydropastea read Phaio, Neum. Can. Ent. 1894, p. 335-type longipennis,-which has precedence.

## 768 a. Athria aner, sp. n.

Ethria carnicaudn, Hmpsn. Cat. Lep. Phal. i. p. 349 ( $\delta^{\circ}$ ), nec Butl.
ठ. Head, thorax, and abdomen black; palpi in front, sides of frons, basal joint of antennæ below, and patches on shoulders and fore and hind coxæ white; abdomen with dorsal series of brilliant blue hands, the anal tuft crimson;
the ventral surface of first three segments white, followed by slight sublateral spots and a spot at base of anal tuft. Fore wing hyaline, the veins and margins black, the base metallic blue; the basal area black, with irregular oblique outer edge ; a black discoidal bar ; the terminal black band slightly expanding below vein 2. Hind wing hyaline, the veins black; the apical area black, broadly at costa, narrowing to a point at vein 1 .

Hab. Venezuela, Caura Valley (Klages), 2 ot type. Exp. 30 mm .

Page 361. Gundlachia being preoccupied (Pfeiff. Moll. 1849), Burtia will stand.

Page 363. Desmidocnemis rename Hyalomis, n. n., the former being a synonym of Herea and Prittwitzi=xanthogaster.

## 847 a. Teucer hypophcea, sp. n.

$\delta$. Head, thorax, and abdomen black; back of head with two yellow spots ; patagia and prothorax with slight greyish streaks; metathorax with greyish patch; pectus and fore coxæ with whitish patches; abdomen with the anal tuft white at extremity, the ventral surface whitish at base. Fore wing black, suffused in parts with grey, especially on terminal area; discocellulars grey; a quadrate hyaline patch in end of cell, an elongate patch below the cell, a slight streak above base of vein 2 , and four patches beyond the cell between veins 7 and 3. Hind wing black, with hyaline patches in and below cell ; the underside with white patches in and below cell, the fold on inner area white, the rough hair on terminal area greyish.

Hab. Venezuela, Caura Valley (Klages), 1 ठ type. Exp. 26 mm .
906. Napata euchloa, n. n. for the Jamaican species, $N$. chalybea from Cuba being distinct.

Page 413. For Patreliura read Trichromia, Hübn. Verz. p. 164 (1827) -type capys, -which has precedence.

948 a. Ixylasia semivitreata, n. n.
Autochloris almon, Hmpsn, Cat. Lep. Phal. B. M. i. p. 432 (nec Cram.).
Hab. Brazil, Rio Janeiro (Fry), 1 太 type, Blumenau, 1 ㅇ.

Page 432. Delete Autochloris, Hüln. The genus will stand as Schasiura, Butl.

## 1001 a. Trichodesma albicincta, sp. n.

ठ. Head, thorax, and abdomen black-brown; palpi in front and frons yellowish white; tegulæ in front and shoulders yellow; patagia with slight yellowish streaks; pectus and legs mostly white ; abdomen with fine white segmental rings, the ventral surface white, except anal segment. Fore wing black-brown ; the costa, veins, and submedian fold with fine pale streaks on basal half; an oblique yellow band across end of cell from below costa to vein 2. Hind wing black-brown, with some yellow suffusion in and below cell; a rather oblique yellow patch beyond the cell. Underside with slight white suffusion at base of both wings.

Ilab. Venezuela, Caura Valley (Klages), 1 ठ type. Exp. 30 mm .

Page 47t. Insert Azatrephes, n. n., for Zatrephes, Hmpsn. (nec Hübn.).
1050. Azatrephes paradisea, insert Malisidota discalis, Wlk. vii. 1706 (1856), which has precedence.
1051. Zutrephes nitida is an Arctid near Premolis.

Page 478. For Neacerea read Delphyre, Wlk. ii. 537 (1854)-type hebes; and insert Nodoza, Schaus, J. N.Y. Ent. Soc. iv. p. 150 (1896)-type tristis.

Delphype hebes, Wlk. ii. 537 (1854), = Nodoza tristis, Schaus, J. N.Y. Ent. Soc. iv. p. 150 (1896).
1074. Rename Eucereon metoidesis, n. n., and delete E. cinctum, Schaus.
1086. Eucereon balium. Transfer to Heliura after zonata.

## 1087 a. Eucereon dorsipuncta, sp. n.

Head and thorax grey; palpi blackish; frons, vertex of head, and tegulæ with black spots, back of head with pair of yellow spots; patagia slightly streaked with black; legs fuscous and white, the coxæ tinged with crimson; abdomen
crimson, with dorsal series of small black spots and the anal segment black, lateral black stripes, and the ventral surface yellowish white. Fore wing white, the veins, costal and inner areas tinged with pale brown; subbasal black spots below costa and cell, the latter followed by a black streak above vein 1; antemedial black spots on costa, below cell, above and below vein 1, the spot above vein 1 displaced outwards; a spot in middle of cell with pale centre or divided by a pale streak; a spot on costa above end of cell and two beyond the cell, an oblique series from vein 5 to imner margin, the spots above and below vein 4 wedge-shaped ; a postmedial series of irregular spots, wedge-shaped below costa and streak-like above inner margin; a subterminal series of spots and terminal series of points. Hind wing white, the terminal area fuscous, broad at costa, narrowing to a point near tornus.

Hab. Venezuela, Caura Valley (Klages), 1 ō, 1 ¢; Paraguay, Sapucay (Foster), 3 of type. Exp. 34 mm.
1119. Eucereon ochrota, n. n. for the Jamaican species, E. guacolda from Cuba being distinct.

## 1157b. Ctenucha nantana.

Ammalo nantana, Whk. xxxi. 282 (186t); Butl. Ill. Het. B. M. i. p. 54 , pl. xix. fig. 2.
Ctenucha rubicunda, Dognin, Le Nat. 1905, p. 10.
Hab. Brazil, Amazons, Nauta; Peru.

## 1180 a. Hyaleucerea phceosoma, sp. n.

$\delta$. Head and thorax olive-brown, tinged with fuscous; neck with crimson ring ; palpi yellowish white at base ; coxæ whitish, femora with whitish stripes, tarsi with pale rings; abdomen fuscous, with a bluish tinge, the ventral surface white. Fore wing black-brown, the veins streaked with olive; ill-defined olive streaks from base below costa and cell and a spot on costa before middle; a hyaline patch towards end of cell, divided by a dark streak in discal fold; hyaline patches below the cell before vein 2 and above its base; hyaline spots beyond the cell above and below vein 6 and further from base above and below vein 4 ; a waved olive subterminal line bent outwards to near tornus between veins 6 and 5 ; a slight apical spot. Hind wing hyaline ; the veins black; the terminal area broadly blue-black, the hyaline
extending to near termen between veins 5 and 2 ; cilia whitish at tips.

Hab. Paraguay, Sapucay (Foster), 2 ot type. Exp. 30 mm .

## Arctiadæ.

## Nolinex. (Vol. II.)

## 74 a. Nola bicincta, sp. n.

б. Head and thorax white ; palpi yellow-brown ; pectus, legs, and abdomen fuscous. Fore wing white; the costa with irregular yellow-brown and fuscous fascia ; an oblique yellow and black antemedial band, with a tuft of black scales on its outer edge in cell; a postmedial nearly erect yellow and black band, expanding to costa, and with its outer edge indented above vein 2 ; some fuscous on termen towards apex. Hind wing pale fuscous.

Hab. Cape Colony, Deelfontein (Col. Sloggett), 1 ot type. Exp. 18 mm .

## 157 a. Zia hemipheea, sp. n.

ㅇ. Head red-brown, with the vertex white and a white bar across frons; tegulæ red-brown and grey, white at sides; thorax white; abdomen grey and white. Fore wing with the basal area white to one third of costa and half of inner margin, and with some grey striæ on costa; the terminal area silvery grey, with some red-brown on medial part of costal and terminal areas, and a white patch with some grey spots on it from apex to middle of postmedial line; the white area bounded by a rufous line, slightly angled outwards in submedian fold; the postmedial line represented by some small dentate black marks between veins 7 and 2 ; subterminal line waved, white, interrupted, with some small patches of black scales before it at middle; a series of silvery striæ just before termen. Hind wing pale fuscous.

Hab. Java, Arjuno, 3000 feet (Doherty), 1 i type. Exp. 20 mm .

## Genus Eurynola, nov.

Type, E. mesoleuca, Lower, Tr. R. Soc. S. Austr. 1903, p. 39.
Proboscis fully developed; palpi obliquely upturned, rather thickly scaled; antennæ of male bipectinate, the apical third sinule. Fore wing with veins 3 and 5 from near
angle of cell; 6, 7 from cell; 8, 9, 10 stalked; 11 curved. Hind wing with veins 3,4 stalked; 5 from just below middle of discocellulars ; 6, 7 shortly stalked.

## Lithostane.

## 229 b. Phryganopsis unipuncta, sp.n.

Antenne of male bipectinate, of female minutely serrate.
Head and thorax brownish ochreous; fore and mid legs suffused with fuscous; abdomen yellowish white. Fore wing ochreous, suffused with brownish ; a small round black discoidal spot. Hind wing yellowish white.

Hab. Algeria, Hammam-es-Salahin (Walsingham), 2 ठ, 4 \&, type. Exp. 20 mm .

## 248 a. Phreosia orientalis, sp. n.

$\delta^{7}$. Fore wing with the cell very narrow, with a fold in it and fringe of scales on upperside; the inner margin strongly lobed before middle.

Head, thorax, and abdomen fulvous yellow, the last greyish towards base. Fore wing orange-yellow, the area below the cell flesh-coloured; a small rather elongate blackish patch above end of cell. Hind wing orange yellow, the terminal area paler.

Hab. Borneo, Kuching (Shelford), 1 đ type. Exp. 26 mm .

## 342 a. Ilema fuscifrons, sp. n.

ठ. Head, tegulæ, and shoulders orange-yellow ; palpi, frons, and antennæ fuscous; thorax grey; pectus and legs yellow, the fore legs and mid tibiæ in front grey; abdomen yellow. Fore wing grey, the costa narrowly fulvous yellow, the costal edge black towards base; cilia yellowish. Hind wing yellow. Underside of fore wing as on upperside, but the basal and inner areas yellower.

Hab. Br. N. Guinea, Aroa R. (Meek), 1 ठ type. Exp. 32 mm .

## Page 219. Genus Parashada, nov.

Proboscis fully developed; palpi porrect, not reaching beyond the rounded frontal prominence, which has a small corncous plate below it; antennæ of male with cilia and bristles ; tibiæ with the spurs moderate. Fore wing of male with large costal fold on underside fringed with hair; the
neuration extremely distorted; vein 2 from middle of cell, after vein 3 the median nervure is curved upwards and backwards to the lower edge of the very large areole before its extremity, from which arise veins 4,$5 ; 6$ from areole ; 7, 8 , 9 stalked, 7 from beyond $9 ; 10,11$ from areole. Hind wing broad, the costal area highly arched; the cell very narrow ; vein 2 from before middle; 3, 4 shortly stalked; 5 absent; 6, 7 coincident ; 8 much curved.

## 457 a. Parashada truncata, sp. n.

ठ. Head and thorax orange-yellow; abdomen fuscous brown, the ventral surface orange-yellow. Fore wing dull reddish brown. IIind wing with the costal half pale yellow, the inner half dull brown.

Mab. Sula Mongoli (Doherty), 1 б type. Exp. 24 mm .

## 521 a. Cisthene triplaga, sp. n.

Black; tegulæ orange; abdomen with subdorsal orange patches on second segment and lateral and ventral stripes, except on terminal segment. Fore wing with rather broad orange fascia on median nervure, expanding somewhat at lower angle of cell, and with its lower edge somewhat diffused; a curved subterminal series of three spots. Hind wing with broad orange fascia in and below cell from base to well beyond cell.

Hab. Paraguay, Sapucay (Foster), 2 of, 1 of type. Exp. 30 mm .

Page 258. For Stictane read Manoba, Wlk. Journ. Limn. Soc., Zool. vii. p. 62 (1863)-type implens.

## 542. Manoba implens.

Manoba implens, Wlk. Journ. Linn. Soc., Zool. vii. p. 62 (1863);
Hmpsn. Cat. Lep. Phal. B. M. ii. p. 46, pl. xix. fig. 22.
Stictene junctilinea, Hmpsn. A. M. N. H. (7) viii. p. 183 (1901).

## 696. Eurosia accepta.

The male has simply ciliated antennæ.
E. acanthocera, 11. n., for the species from Sangir with the tooth and sinus to antenne.

## Page 339. Genus Chrysocyma, nov.

Type, C. mesopotamia.
Proboscis absent; palpi extending to just beyond frons and clothed with long hair ; antennæ of male with very long rather widely separated branches; hind tibiæ with one pair of spurs and fringed with long hair on outer side. Fore wing short and broad, the apex rounded; veins 3 and 5 from near angle of cell ; 6 from upper angle; 7, 8, 10 stalked; 9 absent; 10 from near apex, 11 from cell. Hind wing with veins 3,4 from angle of cell ; 5 from well above angle; 6, 7 stalked; 8 from towards end of cell.

714 a. Chrysocyma mesopotamia, sp. n.
Deep orange; antennæ with the branches blackish. Fore wing with two subbasal, two antemedial, and two postmedial pale waved lines; a small blackish discoidal spot.

Hab. Zanzibar, 1 б ; Br. C. Africa, Chinde (De Jersey), 1 бै ; Mashonaland, Salisbury (Dobbie), 3 ot type. Exp. 24 mm .

## 751 a. Prepiella procridia, sp. n.

ठ. Head and thorax fuscous, shot with metallic green ; abdomen fuscous, the tufts on third segment fulvous, the ventral surface shot with metallic green. Fore wing fuscous, the costal half and termen suffused with golden metallic green. Hind wing fuscous brown, the hair on tornal lobe fulvous.

Hab. Paraguay, Sapucay (Foster), 1 ठे type. Exp. 20 mm .

## 754 a. Prepiella radicans, sp. n.

б. Head and thorax yellow; antennæ black except at base ; fore and mid tibie with black bands; abdomen yellow, slightly tinged with crimson. Fore wing bright yellow, with slight crimson streaks in discal and submedian folds; the terminal area tinged with crimson; a black spot at base of costa, followed by a black streak below costa ; short black streaks on the veins before the antemedial line, which is oblique from costa to submedian fold, then incurred ; postmedial line irregular, oblique from costa to subterminal line at vein 4, and emitting short streaks on the veins, then finer, retracted along vein 3 to below end of cell near antemedial line, and giving off a fine streak on vein 2, then excurved
below submedian fold; a curved subterminal line; cilia fuscous. Hind wing yellow, tinged with crimson.

Hab. Br. Gutana, Bartica (IV. J. Kaye), 1 ot type. Exp. 16 mm .

769 a. Illice triplaga, sp. n.
$\delta$. Head yellow, the third joint of palpi, frons, and antennæ (except basal joint) black; tegulæ and patagia yellow, thorax fuscous; pectus yellow; legs fuscous and yellow; abdomen crimson. Fore wing fuscous; a yellow patch on basal half of inner margin ; a postmedial conical patch from costa to discal fold and another from vein 2 to inner margin, becoming crimson at margin. Hind wing crimson, with fuscous terminal band from apex, narrowing to a point at vein 2. Underside of fore wing with the patches crimson and confluent.

Hab. Paraguay, Sapucay (Foster), 1 ơ type. Exp. 20 mm .

## 777 b. Illice roseiceps, sp. n.

ठ. Head, tegulæ, and patagia crimson ; frons, antennæ, and thorax fuscous; legs crimson and fuscous; abdomen crimson. Fore wing greyish fuscous; a yellow fascia on inner margin from base to a postmedial triangular patch extending to above vein 2 ; a postmedial wedge-shaped patch from costa to lower angle of cell. Hind wing crimson, becoming yellow near the terminal fuscous band, which is wide at costa, narrowing to a point at tornus. Underside of fore wing with the postmedial patches confluent.

Hab. Paraguay, Sapucay (Foster), 1 ot type. Exp. 24 mm .

## 778 a. Illice rhodocraspis, sp. n.

ठ. Head and thorax grey-brown; palpi (except at tips), tegulæ, pectus, femora, and whole of hind legs crimson; abdomen crimson. Fore wing grey-brown, the costal edge crimson. Hind wing crimson, with rather narrow terminal fuscous band, expanding towards apex and narrowing to a point at tornus.

Hal. Argentina, Sta. Fé, Ocampo (Wagner), 1 ô type. Exp. 16 mm .

## 829 a. Cincia nephelistis, sp. n.

Antennæ of male bipectinate, with moderate branches; hind wing with veins 6,7 from cell. Head and thorax palo
pinkish mixed with black; palpi black; vertex of head and metathorax with black patches; antennæ yellowish white, with the basal joint black in front ; abdomen pink, suffused with fuscous, the base whitish. Fore wing pale pink, thickly irrorated and in places suffused with black; the veins black; the costal area pinker. Hind wing of male white, the costal and apical areas suffused with fuscous, of female wholly suffused with fuscous.

Hab. Cuba, Santiago, 1 i ; Mutijas, 1 ơ (Schaus) type. Exp., ơ 24, ㅇ 26 mm .

## Page 414. Genus Microhyle, nov.

Type, M. fadella, Mab. Le Nat. ii. p. 100 (1882).
Proboscis moderate; palpi upturned, hardly reaching vertex of head, the third joint acuminate; antenne of male bipectinate, with very long branches; tibiæ with the spurs long. Fore wing with vein 2 from middle of cell, 3 from before angle, 5 from above angle, 6 from upper angle; 7, 8 , 10 stalked from before angle ; 9 absent; 11 free. Hind wing with vein 2 from middle of cell; 3, 4 coincident; 5 from well above angle; 6, 7 on a long stalk; 8 from middle of cell.

## Page 421. Genus Opsaroa, nov.

## Type, O. fulvinota.

Proboscis absent ; palpi porrect, not reaching beyond frons, and clothed with long hair ; frons with long hair; antenne of male with very long branches, ending in two bristles and decreasing rather suddenly to apex; fore tibire with long process arising from base; hind tibiæ with one pair of spurs; abdomen clothed with long hair. Fore wing with vein 3 from long before angle of cell; 5 from above angle ; $6,7,8$ stalked; 9 absent; 10, 11 from cell. Hind wing with veins 3,4 from angle of cell ; 5 from well above angle ; 6, 7 coincident; 8 from close to end of cell.

## 891 a. Opsaroa fulvinota, sp. n.

ठ. Head and thorax clothed with greyish-brown hair; patagia with some fulvous hair at extremity; abdomen clothed with orange hair, greyish at base. Fore wing sparsely clothed with red-brown hair; an elongate fulvous-yellow mark in and beyond end of cell, with a prominent black discoidal spot on it; an elongate fulvous-yellow patch in submedian interspace from below origin of vein 2 to near
termen. Hind wing fulvous orange, the costa, termen, and cilia (except towards tornus) reddish brown.

Hab. Cape Colony, Triangle, 2 of type. Exp. 22-24mm.

## 915 a. Asura chrysomela, sp. n.

$\delta^{2}$. Fore wing with the costa highly arched just beyond middle, the upper angle of cell much produced.

Black; head, greater part of tegulæ, shoulders, front of pectus, fore legs (except part of tibiæ), extremity of mid and hind femora, hind coxæ, and anal tuft orange. Fore wing with broad orange medial band from subcostal nervure to inner margin, its immer side extending to costa and sinuous, its outer angled outwards at vein 4 . Hind wing with orange medial patch on costal area.
i. Fore wing with the orange band very broad from costa to inner margin, its outer edge angled at veins 6 and 4. Hind wing with very broad orange-yellow band from medial part of costa to tornus.

Hab. Solomon Is., Choiseul (Meek), 1 む̃, 1 \& type. Exp., ठ 30, ㅇ 36 mm .

## 928 a. Asura hemachroa, sp. n.

$\delta$. Head, thorax, and abdomen crimson ; vertes of head, tegulæ, patagia, metathorax, and extremity of fore tibir with fuscous points. Fore wing crimson ; three black points at base, followed by a slight streak in submedian fold ; the lines rather broad, fuscous slightly defined on each side by ochreous; the antemedial line acutely angled outwards in cell, then oblique and sinuous; the medial line strongly angled outwards on median nervure, then incurved; the postmedial line very oblique from costa to vein 4 , where it is angled outwards, then strongly angled inwards in submedian fold; a subterminal series of fuscous spots on an ochreous ground, slightly angled outwards at veins 6 and 4. Hind wing paler crimson.

Hab. Solomon Is., Bougainville (Meek), 2 す type. Exp. 18 mm .

## 929 a. Asura metascota, sp. n.

Head and thorax orange-scarlet, with slight fuscous spots on vertex of head, tegula, patagia, thorax, and extremity of tibiex and tarsi ; abdomen fuscous, with the extremity scarlet. Fore wing scarlet, with three black points at base and fuscous
subbasal patches below costa and cell; an incomplete antemedial line, angled strongly outwards in cell, then oblique and slightly angled inwards in submedian fold, more or less connected by fuscous suffusion with the similar somewhat waved and diffused medial line ; postmedial line oblique from costa to vein 3 , then inwardly oblique and angle 1 inwards in submedian fold, and more or less connected by fuscous streaks with the diffused subterminal line, which is angled outwards on veins 6 and 4 and inwards in submedian fold; cilia fuscous. Hind wing uniform fuscous; the underside with some red suffusion on basal half of costal area.
$A b$. 1.-Fore wing suffused with fuscous, leaving some red at base, some ante- and postmedial points, three medial spots, and some irregular terminal marks.-Bougainville.

Hab. Solomon Is., Choiseul I. (Neek), 1 ठ, 1 \& type; Bougainville (Meek), 1 ठ․ Exp., ठ 30, 우 36 mm .

## $106 \pm a$. Eutane nivea, sp. n.

ㅇ. Frons orange; vertex of head and thorax pure white; legs tinged with fulvous; abdomen white, tinged with yellow towards extremity. Fore wing pure white, the costa narrowly orange ; a black point on discocellulars; the termen and cilia orange, with a series of black striæ before the former, expanding into a spot at vein 2, and a series of black and silver strix at base of latter. Hind wing white, the cilia tinged with yellow. Underside of fore wing with the costal area tinged with yellow, the disk with fuscous.

Hab. Pulo Laut (Doherty), 1 \& type. Exp. 20 mm .

## Page 538. Genus Melastrota, nov.

Type, M. nigrisquamata, Swinh, A. M. N. H. (7) vii. p. 467 (1801).
Proboscis fully developed; palpi porrect to just beyond frons; antennæ of male ciliated; hind tibire with the spurs long. Fore wing rather short and broad; vein 2 from towards angle of cell oblique, 3 from before angle, 5 absent, 6 from below upper angle; 7, 8 and 9,10 stalked, 11 anastomosing with 12 ; male with the subcostal area to end of cell and upper part of cell clothed with black scales on underside. Hind wing with vein 2 from before middle of cell; 3,5 absent ; 6,7 stalked ; 8 from middle of cell.

## Arctiante. (Vol. III.)

## 1214a. Aphyle cuneata, sp. n.

d. Antennæ serrate, the apical third simple; hind wing
with veins 3,5 from cell. Head and thorax white, tinged in parts with buff; palpi black behind; tegulæ with blackish line near base, incomplete at middle, a brown medial line and blackish line at tips; patagia with two blackish bars; mesoand metathorax with paired fuscous spots; abdomen vermilion, the anal tuft and ventral surface white. Fore wing white, the base, costal and terminal areas tinged with buff; the veins buff, with dark streaks on veins $4,5,6$; some vermilion on basal inner area; a blue-grey band at base from costa to vein 1; an oblique subbasal band from below costa to vein 1, followed by a black point in cell and brown line from cell to vein 1, then a black bar from cell to vein 1; a black streak on middle of inner margin, narrowing towards base; a black point in middle of cell and short black streaks above and below base of vein 2; a black discoidal bar ; a subterminal series of small black spots, excurved from below costa to termen below vein 4, and the spots above veins 4 and 5 connected with termen by short streaks, the series then incurved and represented by an oblique striga above vein 3, a spot above vein 2, one nearer termen below vein 2, and two conjoined spots at tornus. Hind wing hyaline white, the inner area suffused with vermilion, the cilia yellowish.

Hab. Br. Guiana, Potaro R. (Roberts), 1 б type. Exp. 36 mm .

## Page 27. Genus Zatrephes.

Zatrephes, Hübn. Verz. p. 171 (1827). Type, nitida.
Proboscis well developed; palpi upturned to near vertex of head and rather thickly scaled; antennæ of male bipectinate with moderate branches, of female with shorter branches; tibie fringed with hair, the tarsal joints with slight tufts of hair. Fore wing with veins 3, 4 from angle of cell, or 3 from just before angle ; 5 from above angle; 6 from upper angle ; 7, 8, 9, 10 stalked, 7 from beyond $10 ; 11$ from cell: Hind wing with vein 2 from towards angle of cell; 3,5 from angle ; 4 coincident with 5 or abnormally given off just before termen; 6, 7 coincident or forking near termen; 8 arising free, then anastomosing with cell.

> Sect. I.-Fore wing with the termen evenly curved.

$$

## 1227 b. Zatrephes dithyris, sp. n.

む. Head and thorax pale flesh-brown, irrorated with crimson;
abdomen crimson, with whitish dorsal streak on basal segments and slight segmental lines on terminal, the ventral surface whitish. Fore wing flesh-colour, irrorated with crimson; a nearly straight, erect, pale brown antemedial line; a broad medial band and black discoidal point; traces of a fine irregular postmedial line with hyaline points on it above and below vein 4 ; an indistinct subterminal line, incurved and diffused below vein 5. Hind wing crimson, the costa and cilia pale yellow. Underside yellowish white, with slight crimson irroration and suffusion ; hind wing with veins 6, 7 forking before termen.

Hab. Cayenne, St. Jean Maroni (Schaus), 1 of type. Exp. 34 mm.

> Sect. II.-Fore wing with the termen produced to an angle at vein 5, then excised in male.

## 1227 c. Zatrephes flavida, sp. n.

$\delta^{\top}$. Head and thorax yellowish white, the head, metathorax, and fore tibie irrorated with crimson ; mid and hind tibiæ and tarsi with brown spots; abdomen pale yellow, with slight crimson irroration towards extremity, the ventral surface white. Fore wing very pale greenish yellow; costal edge crimson; some faint strix on terminal area; a pale greenish antemedial line, slightly excurved below costa, then oblique; a similar postmedial line, incurved below vein 4, with a bifid, crimson-edged, hyaline spot beyond it between veins 5 and 3 ; a similar minute spot sometimes present above middle of vein 6; cilia irrorated with crimson and tipped with pure white below the angle. Hind wing ochreous yellow, the termen and cilia brown; the underside white, the inner area tinged with yellow.

Hab. Cayenne, St. Jean Maroni (Schaus), 1 of type. Exp. 34 mm .

## 1227 d. Zatrephes trilineata, sp. n.

ठ. Head and thorax brownish ochreous, slightly irrorated with crimson; metathorax with brown crest; pectus and legs white ; fore tibiæ brown, irrorated with crimson ; abdomen brownish ochreous, slightly irrorated with crimson towards extremity, the ventral surface white. Fore wing ochreous, irrorated with crimson, the terminal area striated with greenish brown; a slight greenish subbasal line; three prominent oblique greenish lines on medial area; two hyaline bidentate postmedial spots between veins 5 and 3 , with some blackish

Ann. \& Mag. N. Hist. Ser. 7. Vol. xy.
on their outer side and slight greenish line from them to inner margin, a pair of peints above 5 and a small spot above 6 with point above it; cilia intersected with white towards apex and white-tipped below the angle. Hind wing pale yellow, the medial terminal area tinged with crimson, the cilia brownish; the underside white, with the imner area tinged with yellow.

아. Fore wing with the termen not excised below the angle, more thickly irrorated with crimson, the outer of the three lines slightly excurved below costa and vein 5 ; the liyaline spots reduced to those above veins 6 and 4 .

Hind wing with veins 6, 7 forking just before termen; female with veins 4,5 forking just before termen on left side only.

Mab. ('ayenne, St. Jean Maroni (Schaus), 1 б type; Surinam R., Geldersland, type of in Coll. Schaus. Eap., ठ 34 , ㅇ 42 mm .

## 1245a. Arcomolis sanguinea, sp. n.

Antennre of male serrate and fasciculate; hind wing with the tornus produced to a very large lobe clothed with rough hair and scales above and below, the termen excised before it ; veins 6, 7 shortly stalked, 8 from before middle of cell, sinuous; of female, 6,7 coincident and 8 stalked with them to near apex.

ठ. Head and thorax scarlet, mixed with yellow ; palpi with the first joint white in front, the second and third ochreous; pectus and legs white ; fore coxæ, extremity of femora, tibiæ, and first joint of tarsus on inner side scarlet, the rest of femora on inner side brown, the other tarsal joints scarlet, with white rings ; mid tibiæ (except at base) and tarsi on outer side scarlet; hind tibiee at extremity on outer side and rings on tarsal joints scarlet ; abdomen crimson, the second, third, and fourth segments dorsally brown, the ventral surface white. Fore wing scarlet, striated with yellow, and the interspaces beyond the cell streaked with yellow, the costal edge white ; an antemedial series of four indistinct purplish-tinged spots; a medial maculate purplish band from below costa to above inner margin, towards which it narrows, edged by yellow lines and angled outwards below vein 3 ; a curved series of small purplish yellow-edged spots from below costa to vein 3 near the medial band; cilia yellow at tips. Hind wing crimson; the area covered by fore wing pale brownish, the inner margin brownish yellow.

ㅇ. Wholly crimson above; fore wing with the costal area
suffused with fuscous, prominent interrupted yellow streaks in the interspaces, the maculate bands more distinct, the antemedial bent round to base below cell and the spot in cell separate, the medial more broken up and irregular, the spots towards inner margin elongate; a terminal series of brown streaks on the veins. Hind wing wholly crimson.

Hab. Cayenne, St. Jean Maroni (Schaus), 1 of type, type of in Coll. Schaus. Exp., of 36, i 40 mm .

## 1246 a. Parevia metachryseis, sp. n.

Antennæ of male with very short branches, ending in a bristle; hind wing with veins 6,7 coincident.

Head yellow; palpi tinged with crimson; antennæ brownish ; thorax brown, pectus and legs yellow ; abdomen yellow, dorsally crimson except at base and extremity, some dorsal black points on basal segments and a bar on anal segment. Fore wing purple-brown; the base of inner area yellow ; small crimson-ringed yellow spots before middle above vein 1, at middle above imer margin, and beyond middle above and below vein 1; a truncate triangular yellow patch from middle of costa to median nervure; postmedial and subterminal yellow spots on costa and a triangular patch on termen from above vein 4 to vein 1, its apex pointing towards the postmedial costal spot ; apical half of cilia brown, with some crimson points. Hind wing yellow, the terminal area fuscous from middle of costa narrowing to a point at tornus.

Mab. Surinam, Maroni R., St. Laurent, type oi in Coll. Schaus; Surinam R., Geldersland (Schaus), 1 ot type. Exp. 22 mm .
1386. Elysius pyrosticta, n. n.

Elysius hermia, Hmpsn. Cat. Lep. Phal. B. M. iii. p. 110 (1901).
The South Brazilian species is distinct from Cramer's.
1543. Neritos macrostidza, n. n., for the male described and figured ; female similar except for sexual characters.

1543 a. Neritos onytes $q=p$ samas of has the antennæ pectinated and the structural characters as in repanda except that the brand is elongate.
$\delta$ with the yellow patches on costa and termen confluent or separate; hind wing in both sexes brown.

$$
30^{*}
$$

## 1544a. Neritos discobola, sp. n.

Antennæ of male serrate and fasciculate; fore wing with the fovea elongate, veins 10,11 from cell; hind wing with the costa strongly lobed.

Head yellow; thorax brown; pectus and legs yellow; abdomen scarlet, the base, anal tuft, and ventral surface yellow. Fore wing with the basal area purple-brown from one third of costa to tornus, its outer edge angled at lower angle of cell and vein 3 ; some crimson at base of inner margin; the apical half yellow, with large round purplebrown subapical patch, with some crimson above it on costa, its outer edge waved. Hind wing crimson.

Hab. Venezuela, Aroa, 1 §, 1 if type. Exp., ठ 24, ㅇ 26 mm .

## 1544b. Neritos leucoplaga, sp. n.

Antennæ of male bipectinate with short branches, the apical third serrate, of female serrate ; fore wing with veins 10,11 stalked, the fovea of male elongate; hind wing with the costa strongly lobed and extending to three fourths of wing; veins 3, 5 very shortly stalked.

Pale ochreous brown; verte of head orange-yellow; fore coxre yellow; abdomen with en egmental yellow lines on terminal segments, the anal tho. jellow, the ventral surface pale. Fore wing with pale rounded patch beyond the cell between veins 6 and 3 ; the veins slightly darker. Hind wing palcr ; underside of fore wing with the basal area pale, a yellowish fascia below costa, a slight discoidal lunule.

Hab. Cayenne, St. Laurent Maroni (Schaus), 1 otype, type 우 in Coll. Schaus. Exp., ठ 36, if 38 mm .

## 1544 c. Neritos holophrea, sp. n.

Antennæ in both sexes pectinate with short branches, the apical third serrate; fore wing with veins 10,11 stalked; male with elongate fovea below cell; hind wing with the costa atrongly lobed and extending to three fourths of wing.

Head, 'orax, and fore wing uniform dark purple-grey ; abdomen and hiruing bluish fuscous, the tuft in fovea of male pure white.

Mab. Cayenne, St. Litent Maroni (Schaus), 1 ot type, type of in Coll. Schaus. 1 p. 34 mm .

## 1546 a. Neritos pheoplaga, sp. n.

Antennæ of male with bristles and cilia; fore wing with veins 10,11 stalked, the fovea elongate; hind wing with the costa moderately lobed.

ठ. Head yellow; frons brown; thorax dark brown; pectus and legs white, the fore cosæ yellow in front ; abdomen crimson, the anal tuft yellow, the ventral surface white. Fore wing with the basal area purple-brown from one third of costa to termen above tornus, its outer edge sinuons and angled at lower angle of cell and vein 3 ; a yellow spot edged with scarlet on inner margin before middle; apical area yellow, with rounded purple-brown subapical patch, with scarlet streak on costa above it and bidentate outer edge. Hind wing crimson, with fuscous patch on middle of termen.
¢. Fore wing with the subapical patch joined to the brown area by an oblique subterminal bar.

Hab. Cayenne, St. Laurent Maroni (Schaus), 1 ò type, type $\circ$ in Coll. Schaus. Exp. 22 mm .

## 1550 a. Neritos albicollis, sp. n.

ㅇ. Palpi yellow at base, brownish in front, crimson behind; frons brown; vertex of head yellow, with crimson line behind ; antennæ brown, the basal joint yellow, followed by some crimson; tegulæ pure white; thorax violaceous brown, with small crimson spot on metathorax; pectus, legs, and abdomen yellow, the last dorsally crimson, with some brown at base. Fore wing with the basal area brownish, suffused with purple and white, extending on costa to near middle and thence to termen above tornus, and boundel by a crimson line; a crimson streak just below costa, with an elliptical white patch below it ; a crimson point at base and small crimson and yellow subbasal spots on median nervure and inner margin ; the apical half of wing yellow, with large rounded white-suffused purple patch from apex to vein 3, edged by brown and crimson and with its outer edge rather waved. Hind wing yellow, suffused with crimson, especially towards apex.

Hab. Br. Gulana, Rockstone (Kaye), 1 \& type. Exp. 28 mm .

## 1552 a. Neritos steniptera, sp. n.

Antennæ of male serrate and fasciculate; fore wing long and narrow, especially in male; hind wing with veins 6,7 coincident in male, strongly stalked in femate.

Head and thorax red-brown; palpi with some scarlet above ; vertex of head yellow, with some scarlet round it; tegulæ scarlet at tips; vertex of thorax yellow, edged with scarlet; pectus and legs yellow, marked with brown and scarlet; abdomen yellow, dorsally suffused with scarlet. Fore wing redbrown, with yellow spots, edged with scarlet on fulvous-orange patches; a spot at base; an antemedial series of three conjoined spots forming a band from subcostal nervure to vein 1, excurved at middle; a similar excurved band from middle of costa to median nervure; a series of three spots from vein 5 before termen to vein 2 at termen; cilia with scarlet points towards apex. Hind wing orange-yellow, with fuscous terminal area extending on costa to near middle, narrowing to a point above tornus.

Hab. Cayenne, St. Jean Maroni (Schaus), 1 if type, type $\delta$ in Coll. Schaus. Exp. 30 mm .

## 1552 b. Neritos cyclopera, sp. n.

Antennæ of male serrate and fasciculate; fore wing with the apex produced, the termen oblique; hind wing with vein 7 from before end of cell.

ठ. Palpi yellow, tinged with scarlet behind and with brown spot at extremity of second joint in front; frons brown; vertex of head yellow; thorax purple-brown; pectus and legs yellow, fore femora crimson in front; abdomen yellow, dorsally scarlet, except at extremity. Fore wing with the base dark purple-brown from costa before middle to termen above tornus, its outer edge somewhat angled at lower angle of cell and vein 3 ; the apical area yellow, with large, elliptical, purple-brown, subapical patch, with a little scarlet above it on costa and its outer edges waved. Hind wing orange-yellow, with fuscous terminal band, extending on costa to middle, then sinuous to tornus.

Hab. Cayenne, St. Jean Maroni (Schaus), 1 ó type. Exp. 30 mm .

## 1686 a. Mcenas Fosteri, sp. n.

d. Head and thorax fulvous; sides of palpi and frons, tibix, and tarsi grey-brown; abdomen whitish, the basal half of dorsum fulvous. Fore wing pale brownish ochreous; the costal area rather more fulvous; the cilia white. Hind wing white, with slight fulvous hair at base.

Hab. Paraguay, Sapucay (W. Foster), 2 o type. Exp. 34 mm .

1743 a. Diacrisia metaleuca, sp. n.
ठ. Head and thorax orange-yellow; abdomen orangeyellow, white at base and with ill-defined dorsal fuscous bands. Fore wing uniform orange-yellow. Hind wing pure white.

Hab. W. Africa, Niger R., Anambra, 1 ot type. Exp. 28 mm .

## 1766 a. Diacrisia pulverea, sp. n.

q. Head and thorax orange-yellow; palpi, frons, antennæ, tibiæ, and tarsi fuscous black ; abdomen orange, dorsal and lateral series of black spots on first and terminal segments. Fore wing orange-yellow, finely powdered with brown scales. Hind wing orange-yellow.

Hab. Paraguay, Sapucay (Foster), 2 of type. Exp. $38-42 \mathrm{~mm}$.

## 1844 a. Amsacta seminigra, sp. n.

$\delta^{\sigma}$. Antennæ serrate; head and thorax clothed with rather rough hair ; fore tibiæ very short, the claws conjoined by a curved corneous membrane, so as to form a triangular process.

Head and thorax black; femora scarlet above; abdomen orange, tinged with red towards base; a subdorsal series of blackish spots, becoming bands on terminal segments; a series of lateral spots ; the ventral surface black. Fore wing black; an indistinct darker discoidal lunule and traces of antemedial, medial, postmedial, and subterminal bands. Hind wing white, the marginal areas tinged with yellow and the base of inner margin slightly with red; a small discoidal black spot and two small subterminal spots above tornus.

Hab. Abyssinia, Zegi Tsana (Degen), 1 б type. Eup. 40 mm .

## 1859 a. Estigmene unipuncta, sp. n.

ㅇ. Orange-yellow ; palpi, pectus, and legs grey-brown ; abdomen with dorsal black spots on second, third, and fourth segments; a lateral series and the ventral surface grey-brown. Fore wing with black point at lower angle of cell.

Hab. Germ. E. Africa, Dar-es-Salem, 1 if type. Exp. 38 mm .

## 1866 a. Estigmene internigralis, sp. n.

ठ. Head and thorax dirty ochreous; palpi and frons mostly brown ; tegulæ, stripes on patagia, and dorsum brown ;
pectus mostly brown; femora orange above, the tibiæ and tarsi streaked with brown; abdomen orange, with some brown hair at base and dorsal series of black bands, the ventral surface ochreous. Fore wing ochreous white, more ochreous on costal area; the interspaces from subcostal nervure to submedian fold fuscous black, leaving ochreous streaks on the veins. Hind wing ochreous white, with the interspaces fuscous black except towards base.

Hab. Natal, 1 ot type. Exp. 44 mm .

## 2036 a. Antarctia fulvicollis, sp. n.

б. Head and thorax fuscous; tegulæ edged with fulvous, thorax with dorsal fulvous stripe; pectus fulvous; legs fulvous and fuscous; abdomen fulvous, a dorsal stripe and the ventral surface fuscous. Fore wing fuscous, with some white hairs and some yellowish hair at base. Hind wing yellowish white, the veins and terminal area slightly suffused with fuscous ; cilia fuscous.

Hab. Chile, Llanquihoe (Elwes), 1 ठ夭 type. Exp. 36 mm .

## 2037 a. Antarctia phcoocera, sp. n.

$\delta^{7}$. Head and thorax dark reddish brown; basal joint of antenuæ and a tuft of hair on shoulders orange ; abdomen orange, the ventral surface brown. Fore wing reddish brown, with some orange hair at base of inner margin. Hind wing orange-yellow, the terminal area brown, widely so at costa and narrowing to a point at tornus.
q. Abdomen with diffused dorsal brown bands; hind wing with the orange-yellow area more restricted.

Hab. Paraguay, Sapucay (Foster), 2 む, 1 \& type. Exp., ठ 42, ํ 54 mm .

## Genus Gerarctia, nov.

Type, G. poliotis.
Proboscis fully developed; palpi short, upturned, the second joint moderately fringed with scales in front; frons with rounded prominence ; antennæ of female with bristles and cilia; ccelli present ; tibiæ with the inner spurs rather long; build slender. Fore wing long and narrow ; the cell long; vein 2 from towards end of cell; 3 and 5 from near angle; 6 from below angle; 7 from angle; 8, 9 stalked; 10, 11 from cell. Hind wing with vein 2 from towards end of cell ; 3, 4 stalked; 5 from above angle ; 6, 7 from angle ; 8 coincident with cell to middle.

## 2127 a. Gerarctia poliotis, sp. n.

ㅇ. Head, thorax, and abdomen grey, tinged with fuscous. Fore wing grey, suffused and irrorated with fuscous; the veins with slight dark streaks; the antemedial line very oblique, only defined by the area beyond it being suffused with fuscous; a slight dark streak beyond it in submedian fold ; a slight dark discoidal lunule ; postmedial line whitish, defined on inner side by fuscous streaks on the veins below costa and at middle, bent outwards below costa, then oblique and somewhat angled inwards in submedian fold; a slight oblique dark streak from apex ; a terminal series of black points. Hind wing grey, with rather darker terminal line; the cilia paler; the underside with dark discoidal lunule.

Hab. Canaries, Teneriffe (W. White), 1 i type. Exp. 30 mm .

## Agaristidæ.

## Genus Aprgocera, nov.

## Type, A. argyrogramma.

Proboscis fully developed; palpi upturned, the second joint fringed with long hair in front, forming a pointed tuft at extremity, the third long, porrect, dilated at extremity; frons with truncate conical prominence, with raised rim ; antennæ moderately dilated towards extremity ; eyes smooth; tibiæ nearly smooth and without spines; abdomen with dorsal crests on basal segments. Fore wing with vein 3 from towards angle of cell; 5 from well above angle; 6 from upper angle; 9, 10 anastomosing with 8 to form the areole; 11 from cell. Hind wing with vein 2 from near angle of cell ; 3, 4 from angle ; 5 obsolescent from middle of discocellulars ; 6, 7 from upper angle ; 8 anastomosing with the cell near base only.

## 111a. Apagocera argyrogramma, sp.n.

$\delta$. Head and thorax black; palpi with some white at extremity of first and second joints; sides of frons white ; back of head, tegulæ, patagia, pro-, meso-, and metathorax with paired white spots, patagia fringed with fulvous ; abdomen black, with white segmental lines, the first three segments fulvous, with the dorsal crests blue-black; pectus and femora fulvous, the tibiæ and tarsi fuscous, ringed with white. Fore wing with small black and white patch at base of costal area, then fulvons suffused with fuscous, extending on costa to
middle and on inner margin to near tornus, the outer edge of this area very oblique and sinuous; a small round white spot at upper angle of cell placed between the arms of a silveryblue $y$-shaped mark; an oblique postmedial band of tive white spots from vein 7 to below 3, the three upper spots conjoined. Hind wing bright fulvous red, with rather broad terminal black band, expanding slightly at vein 2 and tapering to a point on inner margin beyond middle; cilia chequered black and white.

Hab. Ashanti, Obuassi (Bergman), 1 ot type. Exp. 62 mm .

## Noctaidæ.

Agrotinte. (Vol. IV.)
Page 10.-Ala being preoccupied (Lock. Crust. 1877), Trichanarta will stand.

## 197 a. Timora albida, sp. n.

Head and thorax white, tinged with pale brown; abdomen white. Fore wing pale yellow-brown; the costal area whitish; a pure white fascia in discal fold from middle of cell to termen, and another in submedian fold; the interspaces of terminal area with white streaks. Hind wing white, the veins and termen suffused with yellow-brown.

Hab. Algeria, Hammam-es-Salahin (Walsingham), 1 ò, 1 \& type. Exp. 32 mm .
320. Euxoa emolliens, n. n. for E. mollis, Staud. (1891), nec Wlk. (1856).

## 848 a. Episilia gaudens, sp. n.

む. Antennæ strongly serrate. Head and thorax brownish grey; basal joint of antemma and thorax pale rufous; palpi black-brown, except at tips; pectus and legs dark brown and purplish red; abdomen grey-brown, the anal tuft rufous. Fore wing grey, tinged with ochreous to beyond middle, then with purple; traces of a double waved subbasal line from costa to submedian fold; an indistinct double waved antemedial line ; claviform represented by a black point at its extremity; orbicular and reniform with grey annuli slightly defined by brown, the former round, the latter with some fuscous in its lower part ; a medial shade, oblique from costa to lower angle of cell; postmedial line double, filled in with
grey, bent outwards below costa and incurved below vein 4 ; subterminal line whitish, defined on inner side by slight dentate dark marks and a brown patch at costa, slightly angled outwards at vein 7 and excurved at middle ; a terminal brown line. Hind wing whitish, tinged with brown, especially on the veins and terminal area; the underside paler, the costal area suffused and irrorated with purplish brown.
f. Fore wing without ochreous suffusion, the medial shade much stronger.

Hab. Java, Preanger, 1 б' type, $\ddagger$ in Coll. Snellen. Exp., む 30, ¢ 34 mm .

## 911 a. Lycophotia strigigrapha, sp. n.

Head and thorax dark brown mixed with grey ; abdomen grey, dorsally tinged with fuscous, ventrally irrorated with brown. Fore wing brownish grey, irrorated with brown; the veins dark, defined by grey streaks; a black streak in submedian fold from base to termen, strongest near base; a black streak in lower part of cell from before middle; the orbicular minute, round, with black centre and grey annulus undefined above; reniform a small black spot very indistinctly defined by grey; black-brown streaks in the interspaces beyond the cell ; some pale points on costa towards apes; a terminal series of slight black points. Hind wing white, the costa and termen tinged with brown, more strongly in female; the underside with the costal area irrorated with brown, a discoidal point and some points on termen.

Hab. Patagonian Andes, Val de Lago Blanco, 4 ô, 2 앙 type. Exp. 36 mm .

## Page 610. Genus Tricheurois, nov.

Type, T. nigrocuprea, Moore, P. Z. S. 1867, p. 52; Hmpsn. Moths Ind. ii. p. 199.
Proboscis fully developed; palpi upturned, fringed with lair in front; frons obliquely rounded; eyes large, hairy; head and thorax clothed with hair only and without distinct crests; mid and hind tibire spined. Fore wing with veins 3 and 5 from near angle of cell; 6 from upper angle ; 9 from 10 anastomosing with 8 to form the areole; 11 from cell. Hind wing with veins 3,4 from angle of cell; 5 obsolescent from middle of discocellulars; 6, 7 shortly stalked.
1126. Protagrotis viralis, insert Agrotis niveivenosa, Grote, Bull. Geol. Surv. v. p. 206 (1879) ; Smith, Cat. Noct. N. Am. p. 131, which has precedence.

Hadentive. (Vol. V.)
1668 a. Morrisonia chryserythra, sp. n.
of. Antenne minutely serrate; head and thorax bright ferruginous red mixed with ochreous; abdomen ochreous, suffused with ferruginous. Fore wing ochreous, almost entirely suffused with bright ferruginons red ; subbasal line whitish, angled outwards in submedian fold and ending at vein 1 ; antemedial line double, filled in with whitish, oblique, angled inwards on median nervure and vein 1; claviform with its extremity defined by whitish; orbicular and reniform large, with whitish amuli, the former rather oblique, elliptical, open above, the latter incomplete below; postmedial line defined by whitish on outer side, minutely dentate, strongly bent outwards below costa and oblique below vein 4 ; subterminal line minutely dentate, angled outwards at vein 7 , dentate to termen at veins 4,3 , and bent outwards to tornus. Hind wing ferruginous red ; the underside paler, with ferruginous spot and traces of curved postmedial line.

ठ. Head and thorax purplish red ; abdomen suffused with red; fore wing purplish red, the markings all indistinct; hind wing pale reddish.
Hab. New Zealand, Middle I., Orepuki (Dunlop), 1 б type. of in Coll. Dunlop. Exp. 42 mm .

## 1685 a. Morrisonia chlorograpta, sp. n.

q. Head, thorax, and abdomen deep purple-brown; tegule with some red-brown before the slight black medial line; patagia mostly red-brown ; pectus clothed with purplegrey hair, tipped with white. Fore wing deep purple-brown, with some red-brown in submedian fold, between the stigmata, and on veins of postmedial area; subbasal line double, filled in with golden green, waved, from costa to submedian fold; antemedial line double, filled in with golden green, waved, oblique from below costa to below cell; orbicular and reniform large, the former oblique elliptical, defined by black and red-brown, and with traces of golder-green amulus, especially below, the latter defined by black and red-lrown and with incomplete golden-green annulus below and on outer side, where it is developed into a prominent lumule; postmedial line double, dentate, filled in with golden-green dentate marks from vein 6 to inner margin, bent outwards below costa and incurved below vein 4; subterminal line represented by a series of dentate goldengreen marks on black patches, connectel with a terminal
series of black spots. Hind wing deep purplish redbrown; the underside whitish, the costal and terminal areas suffused and irrorated with brown; a discoidal lunule and sinuous postmedial line.

Hab. New Zealand, Middle I., Orepuki (Dumlop), 1 ㅇ type. Exp. 56 mm .

## LVII.-Descriptions of new Snakes in the Collection of the British Museum. By G. A. Boulenger, F.R.S.

## Nothopsis affinis.

Rostral twice as broad as deep, not visible from above, its upper angle truncate and narrowly separating the nasals; a pair of internasals, followed by a pair of profrontals, the latter separated from the frontal by three series of small scales; frontal large, cordiform, a little broader than long, with a median cleft in its anterior half; parietals nearly twice as long as the frontal and separated from it by one or two series of granular scales ; two small supraoculars; temporal scales small, granular, keeled; two series of small scales between the eye and the upper labials, which are ten in number ; a pair of very small chin-shields. Scales in 27 rows, obtusely keeled, laterals much narrower than dorsals. Ventrals 162 ; anal entire; subcaudals 98. Greyish yellow above, with a median series of rhomboidal or quadrangular black spots and a lateral series of $\Lambda$-shaped black markings more or less confluent into a zigzag band; head black above; upper lip and lower parts yellowish, dotted with black.
'Total length 320 mm . ; tail 100 .
A single female specimen from Salidero, N.W. Ecuador, 350 feet.

This species is very nearly related to N. rugosa of Cope, to which I had referred the specimen when it was received in 1901. But the British Museum having now acquired an example which I take to be a true $N$. rugosa, from Carriblanca, Costa Rica, I find the Ecuador snake to differ in the feebly keeled scales, the presence of a pair of prefrontal shields, the larger frontal and parietals, and the more feebly angulate ventral shields.

## Phrydors, gen. nov.

Maxillary teeth 22, small, equal; mandibular tecth subequal. Head distinct from neck, moderately elongate, with
vertical sides and projecting edge to the supraocular shield; eye large, with round pupil; a single nasal; no loreal. Body elongate, slightly compressed; scales smooth, with apical pits, in 17 rows; ventrals rounded. Tail rather long; subcaudals in two rows.

This genus appears to be related to Synchalinus, Cope, which is only known to me from the description.

## Phrydops melas.

Snout subtruncate, scarcely longer than the eye, with sharp canthus and vertical loreal region. Rostral broader than deep, scarcely visible from above; nasal large, in contact with the præocular; internasals shorter than the prefrontals; frontal nearly twice and a half as long as broad, a little narrower than the supraocular, longer than its distance from the end of the snout, shorter than the parietals; one preocular, not extending to the upper surface of the head; two postoculars, both in contact with the parietal, which in front is very narrowly separated from the fifth upper labial; temporals $1+2$; seven upper labials, third and fourth entering the eye ; four lower labials in contact with the anterior chinshields, which are shorter than the posterior. Scales in 17 rows. Ventrals 135 ; anal divided; subcaudals 69 . Black above and beneath, head and anterior part of body minutely speckled with brown.

T'otal length 380 mm ; ; tail 105.
A single female specimen from Carriblanco, Costa Rica, collected by Mr. C. H. Lankester.

## Rhadincea Steinbachi.

Rostral broader than deep, just visible from above; intornasals broader than long, shorter than the prefrontals; frontal once and two thirds to nearly twice as long as broad, as long as or a little longer than its distance from the end of the snout, shorter than the parietals; loreal as long as deep or a little deeper than long; one præ- and two postoculars; temporals $1+2$; eight upper labials, third, fourth, and fifth entering the eye; five or six lower labials in contact with the anterior chin-shields, which are as long as the posterior. Scales in 15 rows. Ventrals 142; anal divided; subcaudals 67-69. Grey above ; anterior part of body with a broad dark brown or black vertebral band and a narrower lateral band; head dark brown or black above, with an oblique white spot in front of the eye, another behind the cye, and a third behind the parietals; upper lip and lower parts white.

Total length 540 mm. ; tail 150.
Two specimens, female and young, from the Province Sara, Department Santa Cruz de la Sierra, collected by Hr. J. Steinbach.

## Liophis oligolepis.

Eye large. Rostral broader than deep, visible from above; internasals a little broader than long, shorter than the prefrontals; frontal twice as long as broad, much longer than its distance from the end of the snout, a little shorter than the parietals; loreal deeper than long; one pre- and two postoculars; temporals $1+2$; eight upper labials, fourth and fifth entering the eye; four lower labials in contact with the anterior chin-shields, which are a little longer than the posterior. Scales in 15 rows. Ventrals 152 ; anal divided; subcaudals 61. Olive-brown above, the scales dark-edged; upper lip and lower parts white; a black streak behind the eye, above the posterior upper labials; a black streak along each side of the tail.

Total length 320 mm . ; tail 73.
A single female specimen from Igapé-Assu, Pará, Brazil, collected by M. A. Robert.

## Atractus ventrimaculatus.

Snout obtuse. Rostral small, nearly as deep as broad, just visible from above; internasals very small ; præfrontals as long as broad; frontal as broad as long or a little longer than broad, as long as its distance from the end of the snout, much shorter than the parietals; loreal twice to twice and a half as long as deep; two postoculars; temporals $1+2$; eight upper labials (exceptionally seven), fourth and fifth (or third and fourth) entering the eye; four lower labials in contact with the single pair of chin-shields, which are moderately large and separated from the symphysial. Scales in 15 rows. Ventrals 145-157 in males, 158-159 in females; anal entire ; subcaudals 19-20 in males, 14-15 in females. Olive to blackish brown above, uniform or with dark and light spots; a black vertebral stripe sometimes present; lower parts whitish, much speckled and spotted with black.

Total length 430 mm. ; tail 30 .
Several specimens from Merida ( 1630 m .) and Fuqueros ( 2500 m. ), Venezuela, collected by Señor Briceño.

## Calamaria Gimlettii.

Rostral as deep as broad, the portion visible from above as long as its distance from the froutal, which is as broad as long and three times as broad as the supraocular ; parietals much longer than the frontal; no preocular ; one postocular ; diameter of the eye two thirds its distance from the mouth; four upper labials, second and third entering the eye; first pair of lower labials forming a suture with its fellow behind the symphysial ; both pairs of chin-shields in contact with each other. Scales in 13 rows. Ventrals 239 ; anal entire; subcaudals 11 . Brown above, finely speckled with yellowish; scales of the two outer rows brown in front and white behind ; a pair of yellowish spots on the upper surface of the tail, near its base; upper lip and lower parts white; a brown spot at the outer end of each ventral shield ; a brown longitudinal line between the subcaudal shields.
'I'otal length 265 mm . ; tail 8.
A single female specimen from Kelantan, Malay Peninsula, collected by Dr. Gimlette.

## Elaps princeps.

Eye measuring three fifths to two thirds its distance from the mouth. Rostral broader than deep; frontal broader than the supraocular, once and one third to once and a half as long as broad, shorter than its distance from the end of the snout; parietals longer than the frontal, as long as their distance from the internasals; one pre- and two postoculars; temporals $1+2$; posterior nasal separated from the preocular by the præfrontal; seven upper labials, third much longer than fourth and in contact with the prefrontal, third and fourth entering the eye; four lower labials in contact with the anterior chin-shields, which are shorter than the posterior. Scales in 15 rows. Ventrals 220-228; anal divided; subcaudals 19-22 ( 3 to 5 of the anterior entire). Body with black annuli disposed in threes, subequal in width and separated by wider yellow interspaces; 7 or 8 sets of annuli, separated by red interspaces, which are about twice as broad as the yellow ones; the yellow and red scales brown behind, the former tipped with black; snout yellow, spotted with black ; a narrow black cross-band traversing the eyes, across third upper labials, supraoculars, and frontal; back of the head, including posterior part of frontal and supraoculars, red, the shields edged with brown.

Total length 1220 mm . ; tail 65.
Four specimens from the Province Sara, Department Santa Cruz de la Sierra, Bolivia, collected by Hr. J. Steinbach.

LYIII.-Description of a new Mormyrid Fish from the W'hite Nile. By G. A. Boulenger,.F.R.S.

## Marcusenius Harringtoni.

Depth of body 34 times in total length, length of heal 5 . Head as long as deep; snout rounded, $\frac{2}{7}$ length of head; mouth below nostrils, its width $\frac{1}{4}$ length of head; anterior nostril on a line with lower border of eye, posterior a little lower down; the distance between the anterior nostril and the end of the snout equals that between the posterior and the eye; latter moderate, its diameter ${ }_{5}^{3}$ length of snout and $\frac{1}{2}$ interocular width. Dorsal 31, its origin corresponding to that of anal, its length nearly $\frac{2}{3}$ its distance from head. Anal 33, equally distant from base of ventral and from base of caudal. Pectoral pointed, a little shorter than head, not quite twice as long as ventral. Caudal scaly, with pointed lobes. Caudal peduncle $3 \frac{1}{2}$ times as long as deep, as long as head. 87 scales in the lateral line, $\frac{15}{16}$ in a transverse series on the body, $\frac{14}{14}$ in a transverse series between dorsal and anal, 12 round caudal peduncle. Brown above, white below; dorsal and anal fins blackish, white at the base; a blackish streak along each lobe of the caudal fin.

Total length 305 mm .
A single male specimen.
This well-marked species is named after Sir John Harrington.
LIX.-Descriptions of Four new Freshwater Fishes discovered by Dr. W. J. Ansorge in Angola. By G. A. Boulenger, F.R.S.

## Marcusenius Ansorgii.

Depth of body equal to length of head, $4 \frac{1}{2}$ to 5 times in total length. Head once and $\frac{1}{5}$ as long as deep; snout rounded, $\frac{1}{4}$ length of head; mouth small, terminal, but situated below the level of the eyes; a fecble mental swelling ; teeth small, notehed, 7 in the upper jaw, 10 in the lower; eye shorter than the snout; anterior nostril on a level with centre of eye, posterior lower down and separated Ann. \& Mag. N. Hist. Ser. 7. Vol. xv. 31
from the eye by a space equal to its distance from the anterior. Dorsal 19, originating above 5 th or 6 th ray of anal, its length about 2 $\frac{1}{2}$ times in its distance from head. Anal 24-26, equally distant from base of caudal and from base of ventral, or a little nearer the former. Pectoral obtusely pointed, $\frac{2}{3}$ length of head, once and $\frac{2}{3}$ as long as ventral, not quite reaching base of latter. Caudal with rounded lobes. Caudal peduncle $2 \frac{1}{2}$ or 3 times as long as deep, $\frac{2}{3}$ or $\frac{4}{3}$ length of head. $67-72$ scales in the lateral line, $\frac{13-14}{17-18}$ in a transverse series on the body, $\frac{11}{10}$ between dorsal and anal, 16 round caudal peduncle. Brownish; a blackish vertical bar between origin of dorsal and anal.

Total length 110 mm .
Two specimens from between Benguella and Bihé.
This species is intermediate between M. Lhuysii, Stdr., and M. pauciradiatus, Stdr.

## Gnathonemus angolensis.

Depth of body $3 \frac{1}{2}$ times in total length, length of head 5 times. Head as long as deep, with curved upper profile; snout $\frac{1}{4}$ length of head; mouth small, on a line with lower border of eye; a feeble mental swelling ; teeth small, conical, 5 in the upper jaw, 6 in the lower ; eye $\frac{3}{4}$ length of snout. Dorsal 26, originating above 8th ray of anal, its length $2 \frac{1}{3}$ times in its distance from head. Anal 33, nearer base of caudal than base of ventral. Pectoral pointed, a little shorter than head, twice as long as ventral, reaching base of latter. Caudal scaled in its basal half, with pointed lobes. Caudal peduncle $2 \frac{1}{2}$ times as long as deep, $\frac{3}{4}$ length of head. 53 scales in the lateral line, $\frac{12}{16}$ in a transverse series on the body, $\frac{8}{8}$ between dorsal and anal, 12 round caudal peduncle. Brown above, silvery white beneath; a few irregular dark brown blotches on the body; fins dark brown.

Total length 135 mm .
A single specimen from the Quanza River.
Allied to $G$. senegalensis, Stdr.; distinguished by larger scales.

## Alestes humilis.

Depth of body 31 times in total length, length of head 4 times. Head longer than deep, 2.2 times as long as broad ; snout rounded, shorter than diameter of eye, which is $2 \frac{3}{4}$ times in length of head and equals interorbital width; adipose
eyelid not much developed ; maxillary not quite extending. to below anterior border of eye; length of lower borler of second suborbital equalling diameter of eyc. Gill-rakers moderately long, 20 on lower part of anterior arch. Dirsal II 7, originating above ventrals and at equal distance botween anterior border of eye and root of caudal. Anal III 14. Pectoral fin a little shorter than head, nearly reaching ventral. Caudal forked. Caudal peduncle twice as long as deep. Scales $30{ }_{3_{3}^{2}}^{4 \frac{1}{2}}, 2$ between lateral line and ventral. Olive above, silvery beneath; a black spot on the caudal peduncle, extending on the median caudal rays.

Total length 70 mm .
A single specimen from the Quanza River.
Most nearly related to A. Imberi, Peters. Distinguished by a more elongate body with a greater number of scales in the lateral line.

## Mastacembelus Ansorgii.

Depth of body 26 times in total length, length of head $8 .{ }_{2}^{1}$ times. Vent halfway between end of snout and root of caudal. Rostral appendage trifid and as long as the eye, which is $3 \frac{1}{2}$ times in length of snout; cleft of mouth extending to below centre of eye; no præorbital spine; preoperculum with two or three strong spines. Dorsal XXXIV 128, anal II 120, both confluent with caudal, which is rounded; the distance between the first dorsal spine and the head is 3 times in the length of the latter. Pectoral $\frac{1}{5}$ length of head. 20 scales between the origin of the soft dorsal and the lateral line. Olive-brown above, yellow beneath, with dark brown spots and marblings; three senies of large spots on the back, the lateral series confluent into a wavy band on the tail; below these spots a straight band along the body, disappearing a little in advance of the vent; a band on each side of the head, and a vertical bar below the eye; fins yellow, with dark brown spots and oblique streaks.

Total length 445 mm .
A single specimen from the Quanza River.
The nearest ally of this new species is M. marmoratus, Perugia, from the Congo.

This is the first Mastacembelus recorded from south of the Congo.
LX.-Descriptions of some new Species of Syntomidæ and Arctiadre from Tropical South America. By Herbert Druce, F.L.S. \&c.

## Fam. Syntomidæ.

## Mesothen endoleuca, sp. n.

Malc.-Head, antemne, collar, tegule, thorax, abdomen, and legs black; abdomen with two greyish-blue lines from the base to the anus. Primaries and secondaries hyaline; costal margin, apex, outer and inner margins, and veins all lack; the apex of the secondaries edged with black.-Femule the same as the male, but with simple antennæ.

Expanse 1 inch.
Hab. Venezuela, Caura Valley (T. M. Klages, Mus. Druce).

## Mesothen Ockendeni, sp. n.

Male.-Head, antennæ, and palpi black, front of head white; collar, tegula, thorax, and abdomen orange-yellow ; a black spot at the base of the thorax and one on each segment, the anal segment black; underside of the thorax and legs black. Primaries and secondaries byaline, the veins all black, the apex broadly black, the outer and inner margins edged with black; the apex of the secondaries black.Female identical with the male.

Expanse $1 \frac{3}{4}$ inch.
Hab. S.E. Peru, Santo Domingo, 6000 feet (Mus. Druce).

## Cosmosoma anoxanthia, sp. n.

Male.-Head metallic blue; antennæ black, tipped with white; the front of the thorax orange, spotted with metallic blue; the tegula orange; thorax and abdomen black, the base of the thorax and sides of the abdomen spotted with bright metallic blue; legs black. Primaries lyyaline, the apex and a band crossing the wing from the end of the cell to the anal angle black, veins black: secondaries hyaline, broadly edged with black. Underside as above.

Expanse $1 \frac{1}{4}$ inch.
Mab. Venczuela, Corosita, Caura Valley (T. 11. Klages, Mus. Druce).

## Cosmosoma apennina, sp. n.

Mrate--Ifead, antemns, and palpi black; collar and tegulae
yellow, thorax black; abdomen yellow, banded with black ; anus and legs black. Primaries hyaline, the apex black; a wide yellow hyaline band crosses the wing between the end of the cell and the apex: secondaries hyaline, the apex black.
-Female identical with the male.
Expanse 1 inch.
Hab. S.E. Peru, Santo Domingo, 6000 feet (Mus. Druce).

## Argyroeides flavicincta, sp. n.

Male.-Head, antennæ, collar, tegulæ, thorax, and abdomen black, tegulæ edged with yellowish brown, abdomen banded with yellow on the upper and underside; legs black. Primaries and secondaries brownish hyaline, the costal, outer, and inner margins and veins black. The underside the same as the upperside.

Expanse 1 inch.
Hab. Venezuela, Caura Valley (T. M. Klages, Mus. Druce).

## Hypocladia elongata, sp. n.

Male.-Head, tegulæ, and thorax brown, antennæ black, collar yellow; abdomen yellow at the base, the sides and underside bright red; a wide brown band down the middle from the base to the apex, spotted with darker brown on each side of the band. Primaries dark brown, the veins light brown; a large brownish-white spot beyond the cell crossing the wing from the costal almost to the outer margin; a greyish-white streak at the base of the cell and two small greyish spots near the middle: secondaries hyaline white, the apex, outer and inner margins bordered with dark brown. Underside: primaries brownish black, the light markings much more distinct: secondaries same as above.-Female almost identical with the male, but with simple antennr.

Expanse $1 \frac{3}{4}$ inch.
Hab. Venezuela, Caura Valley (T. M. Klages, Mus. Druce).

## Hypocladia albipuncta, sp. n.

Female.-Head, antennæ, tegulæ, and thorax brown; collar red; abdomen dark brown, with a wide red band on each side extending from the base to the anus; legs brown. Primaries brown; three white spots beyond the cell, the third quite small; a white dot on the inner margin nearest the base: secondaries white, broadly bordered with brown from the apex to the inner margin. Underside as above

Expanse $1 \frac{1}{2}$ inch.
Hab. S.E. Peru, Santo Domingo, 6000 feet (Mus. Druce).

## Diptilon proleuca, sp. n.

Male-Mear, antenne, palpi, tegulæ, thorax, and legs black ; abdomen black, the two seaments at the base yellowish white. Primaries yellowish hyaline, the veins and margins black: secondaries black, with a few yellowish-white hairs on the inner margin.

Expanse 1 inch.
Hab. Venezuela, Corosita, Caura Valley (T. M. Klages, Mus. Druce).

## Urolasia albipuncta, sp. n.

Mule-Head, antennæ, palpi, tegulæ, and thorax blueblack, the front of the head white ; abdomen blue-black, the base, a row of small spots down the middle, and two rows on the underside all white; legs black. Primaries yellowish hyaline, the veins, apex, outer and inner margins black: secondaries hyaline, the apex black.

Expanse $1 \frac{1}{4}$ inch.
Hab. Venezuela, Corosita, Caura Valley (T. II. Klages, Mus. Druce).

## Ceramidia chloroplegia, sp. n.

Male.-Head, antemne, collar, tegulæ, and thorax black, the collar and tegulæ spotted with metallic green ; abdomen metallic green, with two black bands (one on each side) extending from the base to the anus; the underside of the abdomen black, with a white line on each side. Primaries and secondaries black, shot with dark green.

Expanse $1 \frac{1}{2}$ inch.
Ilal. Venezuela, Corosita, Caura Valley (T. M. Klages, Mus, Druce).

## Irylasia pyroproctis, sp. n.

Male.-Head, antenuæ, collar, tegulæ, and thorax black, the collar and tegule spotted with bluish white ; the abdo nen black, the anal segments brick-red, the base, the sides, and underside spotted with white; legs black. Primaries hyaline, the costal, outer, and imer margins and veins all black; a large square-shaped black spot at the end of the cell: secondaries hyaline, the apex and outer margin black; the veins black. Underside as above, excepting a small white streak on the costal margin of the secondaries.

Expanse $1 \frac{3}{4}$ inch.
Mab. Venezucla, Caura Valley (T. M. Klages, Mus. Druce).

## Neacerea pyrozona, sp. 11.

Male-Head, antennæ, collar, tegulæ, thorax, and abilomen black, the base of the thorax yellow, the fourth, fifth, and sixth segments of the abdomen bright red ; the underside of the thoras and abdomen pink. Primaries blackish brown, the veins yellowish; a spot in the cell and four spots nearer the apex greyish white, in some specimens these spots are much more distinct than others: secondaries hyaline at the base, broadly bordered with black at the apes and round the outer margin. The underside of both wings much blacker than the upperside, and the greyish-white marking much more distinct.

Expanse $1 \frac{1}{4}$ inch.
Hab. Venezuela, Corosita, Caura Valley (T. M. Klages, Mus. Druce).

## Neacerea rhodocrypta, sp. n.

Male.-Head, palpi, antennæ, collar, tegalæ, and thorax greyish brown, the collar and tegulæ spotted with black; abdomen and legs black; the underside of the thorax and abdomen yellowish white. Primaries dark brown, spotted with greyish white in the cell and near the apex: secondaries hyaline, broadly bordered with black. The underside of both wings very similar to the upperside. -The female almost identical with the male.

Expanse $1 \frac{1}{4}$ inch.
Hab. Venezuela, Corosita, Caura Valley (T. II. Klages, Mus. Druce).

## Neacerea discalis, sp. n.

Male.-Head, antennæ, palpi, collar, tegulæ, thorax, abdomen, and legs all black, the tegulæ spotted with red at the base, the underside of the thorax and abdomen white. Primaries dusky hyaline, the veins, a large spot at the end of the cell, the apex, outer and inner margius black: secondaries hyaline, broadly edged with black.

Expanse $1 \frac{1}{2}$ inch.
Hab. Venezuela, Corosita, Caura Valley (T. M. Klages, Mus. Druce).

## Neacerea flaviceps, sp. n.

Male.-Head yellow; antennæ and palpi black, palpi yellow at the base; collar, tegulæ, thorax, and abdomen greyish black, underside of the abdomen yellow; legs greyish
black. Primaries brownish black; a semihyaline streak from the base partly along the inner margin; a white band crosses the wing beyond the cell from the costal to the outer margin: secondaries hyaline, broadly bordered with black, shot with dark blue. Underside very similar to the upperside.

Expanse $1 \frac{3}{4}$ inch.
IIch. Venezucla, Corosita, Caura Valley (T. II. K'lajes, Mus. Druce).

## Heliura plucosoma, sp. n.

Male.-Head, antennæ, palpi, collar, and tegulæ dark brown, the back of the head and collar reddish brown; abdomen black, white on the underside; legs black. Primaries brown; a white spot in the cell, a streak below the cell near the base, and four spots crossing the wing near the apex all semihyaline white; the veins all red: secondaries hyaline, broadly bordered with black, the veins black.

Expanse $1 \frac{1}{2}$ inch.
Hab. Venezuela, Corosita, Caura Valley (T. M. Klages, Mus, Druce).

## Heliura zonata, sp. n.

Male.-Head, antemme, and palpi black, back of the head yellow; collar, tegulæ, and thorax grey, edged with black, the base of the thorax yellow; abdomen red, the underside reddish white; the anus and a line on each side of the abdomen black; legs black. Primaries yellowish white ; a brown band crosses the wing close to the base; a wide brown band crosses the wing beyond the middle from the costal margin to the anal angle; the apex brown; the veins all brown: secondaries white, with the apex and outer margin dusky brown.

Expanse $1_{4}^{1}$ inch.
Ilab. Venezuela, Corosita, Caura Valley (T. M. Klages, Mus. Druce).

## Eucereon atrigutla, sp. n.

Male-Head, thorax, and tegulæ greyish white ; antennæ black, collar red, tegulæ with black spot at the base ; abdomen pinkish red, the anal segment black, underside yellowish white; legs blackish. Primaries greyish white, thickly spotted with black; a row of black spots crosses the wing beyond the cell from the costal margin to the apex; four or
five small black spots close to the apex and several along the outer and inner margins: scondaries white, the apex and outer margin black. Underside: primaries dark grey; a white spot in the cell and a row of small white dots beyond the cell, those close to the costal margin the largest: secondaries the same as above.-The female is identical with the male.

Expanse 1 $\frac{3}{10}$ inch.
Hab. Venezuela, Caura Valley (T. M. Klages, Mus. Druce).

## Eucereon leprota, sp. n.

Female.-Antennæ blackish brown ; head, collar, tegulæ, and front part of thorax greyish; base of the thorax and upperside of the abdomen to beyond the middle blackish brown; the sides and lower segments bright red, the anal segment black; the underside of the thoras and abdomen yellowish white; the legs greyish; a row of black dots on each side of the abdomen from the base to the anus. Primaries grey, the base, a round spot in the cell, a broken band at the end of the cell, and a row of spots near the apex all greyish brown; a series of small greyish-brown spots along. the inner margin; a marginal row of small spots extends from the apex to the anal angle: secondaries greyish white, the apex and outer margin broadly bordered with greyish brown. Underside: primaries blackish brown, the pale markings more distinct than above ; the secondaries the same as above.

Expanse 12 inch.
Hab. Venezuela, Caura Valley (T. N. Klages, Mus. Druce).

## Correbia minima, sp. n.

Male.-Head, collar, and tegula yellowish brown; antennæ, thorax, and abdomen black; legs brownish black; the base of the abdomen on the underside yellowish brown. Primaries black; the base and a wide band crossing the wing from the costal margin to the anal angle pale yellowish brown; the fringe black: secondaries semihyaline black, darkest at the apex and round the outer margin. Underside very similar to the upperside, but the brown markings brighter in colour ; secondaries with a small brownish-yellow spot on the costal margin.

Expanse 1 inch.
Hab. Venezuela, Caura Valley (T. M. Klages, Mus. Druce).

## IIyaleucerea leucosticta, sp. n.

Male-Mear, palpi, antennæ, thorax, tegulæ, and abdomen Wack; two white spots at the back of the head and two large white spots on the thorax; the sides of the ablomen and a small spot on the anus white; legs black and white. Primaries black, greyish in the middle and near the apex: secondaries hyaline, broadly bordered with black from the apex to the anal angle.

Expanse $1_{4}^{3}$ inch.
Hab. Venczucla, Corosita, Caura Valley (T. II. Klages, Mus. Druce).

## Fam. Arctiadæ.

1schnocampa deceptura, sp.n.
Mule-Head, antennæ, palpi, collar, tegulæ, thorax, abdomen, and legs brown. Primaries brown, thickly irrorated with minute black scales; a very indistinct submarginal band extends from the apex to the anal angle: secondaries yellowish white, slightly dusky at the apex.

Expanse $1_{4}^{1}$ inch.
Hab. S.E. Peru, Santo Domingo, 6000 feet (1Nus. Druce).

## Ischnocampa flavicosta, sp. n.

Male.-Head yellow ; antennæ and palpi black; collar, tegulex, and thorax fawn-colour, the base of the tegule yellow; abdomen blackish brown, the underside yellow; legs brown. Primaries fawn-colour, the costal margin from the base to the apex yellow; a yellowish indistinct round spot at the end of the cell: secondaries semihyaline white, the costal margin and the apex edged with fawn-colour.

Expanse $1 \frac{1}{4}$ inch.
Hab. S.E. Peru, Santo Domingo, 6000 feet (Mus. Druce).

## Ischnocampa barbata, sp. n.

Male.-Head, antennæ, palpi, collar, tegulx, and thorax pale grey-brown; abdomen and legs brown; anus yellow. Primaries pale greyish brown, with a darker brown band down the middle of the wing extending from the apex to the base; a small brown spot about the middle of the cell: secondaries greyish, clonded with darker brown at the apex.

Expanse 13 ${ }^{\frac{3}{4}}$ inch.
Mub. S.E. Peru, Simto Domingo, 6000 feet (1Mus. Druce).

Metoxanthia threnodes, sp. n.
Male.-Head, antennæ, palpi, collar, tegulæ, thorax, abdomen, and legs black: underside of the thorax, base of the abdomen, and anus yellowish white. Primaries black, becoming hyaline from the end of the cell to the apex: secondaries hyaline, the apex and veins black.

Expanse 1 inch.
Hah. Venezuela, Corosita, Caura Valley (T. M. Klages, Mus. Druce).

## Stidzeras strigifera, sp. n.

Male.-IIead and collar chrome-yellow ; two black dots on each side of the collar ; antennæ, palpi, and thorax brown; abdomen yellow, banded with black near the anus; legs brown. Primaries pale brown, thickly striated with fine yellow lines: secondaries pale yellow, broadly bordered from the apex to the anal angle with blackish brown. The underside of the primaries dark brown, the secondaries similar to the upperside.

Expanse 2 inches.
Hab. Venezuela, Corosita, Caura Valley (T. If. Klages, Mus. Druce).
LXI.—Descriptions of new Species of Sphegidr and Ceropalidæ from the Khasia Hills, Assam. By P. Cameron.
[Concluded from p. 424.]

## Anoplius palades, sp. n.

Black; the lower part of the front, clypeus, and face densely covered with silvery pubescence. Thorax, legs, and abdomen densely pruinose ; the apical segment of the abdomen densely covered with long black hair. Wings hyaline; the radial, cubital, and the lower part from the top of the first recurrent nervure smoky; the first cubital cellule in front is about one third longer than the second; the first transverse cubital nervure roundly curved, the third almost straight and oblique, as is also the second ; the first recurrent nervure received at the base of the apical third, the second shortly behind the middle of the cellule; the transverse basal nervure interstitial. Spines and calcaria black. if.

Length 9 mm .

Anoplius reconditus, sp. n.
Black; the head below the antennae densely covered with silvery pubescence; the hinder ocelli separated from the cyes by double the distance they are from each other. Apex of elypeus and labrum transverse in the middle. Mandibles at base thickly covered with silvery pubescence, the apex smooth and shining; the teeth piceous. Thorax densely pruinose, the median segment with a gradually rounded slope without furrows. Furrows on the meso- and metapleure narrow, but distinct. Wings almost hyaline at the base, the middle fuscous suffused with hyaline, the apex uniformly smoky ; the apical abscissa of the radius long and with a gradually rounded curve; the first cubital cellule in front fully three times the length of the second; the first transverse cubital nersure with a gradually rounded slope above the middle, the lower part being oblique; the third has the lower part rounded and oblique, the upper straight; the recurrent nervures received shortly beyond the middle. Legs pruinose; their spurs black. Base of abdominal segments with broad pruinose bands; the apical segment densely covered with black hair. $i+$

Length 8 mm .
Anoplius adilis, sp. n.
Black; the front and vertex sparsely covered with long fuscous hair, the face and clypeus densely with silvery pile; the eyes parallel, only very slightly converging above; the clypeus transverse, with the sides rounded. Thorax pruinose, shining; the metanotum with a gradually rounded slope and bearing a few long black hairs in the middle. Legs thickly pruinose, the calcaria black. Wings hyaline; the apex from the base of the radial cellule, from the first transverse cubital nervure, and, below, from the end of the first recurrent nervure, smoky. Apical segments of abdomen thickly covered with long black hair. $q$.

Length 10 mm .
In front the first cubital cellule is slightly longer than the second, below slightly shorter than it; the first recurrent nervure is received near the base of the apical fourth of the cellule, the sccond almost in the middle; first transverse cubital nervure straight, oblique, the second roundly curved, the third obliquely curved in front.

Anoplius stimulatus, sp. n.
Black; the inncr orbits from shortly above the antenne
and the sides of the elypeus broadly white; mandibles (except at the apex) and the coxe on lower side yellowish white; the apical half of middle femora (except at the base and apex) red ; the apical two thirds of the first abdominal segment, the whole of the sccond and the base of the third, narrowly in the middle, more broadly at the sides, ferruginous; the fourth and fifth segments have the sides at the base obscure testaccous. Wings fuscous-violaceous, paler at the base; the stigma and nervures black. $\delta$.

Length 15 mm .
Head densely covered with silvery pile ; the eyes distinctly converging above; the hinder ocelli separated from the eyes by a distinctly greater distance than they are from each other. Palpi black. Clypeus broadly roundly convex, its apex transverse, the sides rounded. Thorax densely covered with silvery pubescence; a narrow shining line down the middle of the scutellum; median segment closely, but not very strongly transversely striated. Abdomen pruinose. Second cubital cellule in front shorter than the third; the first and third transverse cubital nerrures roundly curved; the second straight, oblique; the first recurrent received shortly beyond the middle, the second at the base of the basal third of the cellule.

## Anoplius ardescens, sp. n.

Black; the front and vertex sparsely covered with long. black hair, the face and clypeus with silvery pubescence, the hinder ocelli separated from the eyes by double the distance they are from each other; clypeus transverse, the sides rounded. Mandibles at base thickly covered with silvery pubescence, the apex rufous. Palpi black. Median segment obliquely sloped at the apex, thickly covered (especially the apex) with silvery pubescence; there is a short curved furrow on the sides at the base. Legs densely pruinose; the claws have the basal tooth shorter and much stouter than the apical. Wings fuscous-hyaline, the nervures and stigma fuscous. ${ }^{0}$.

## Length 10 mm .

Pronotum longish, the sides behind oblique. Abdominal segments plumbeous grey at the base, smooth and shining; the fourth and fifth ventral segments thickly covered with long black hair ; second cubital cellule almost longer than the third in front; the first and third transverse cubital nervures are roundly curved; the sceond straight, oblique ; both the recurrent nervures are received shortly beyond the middle of the cellules.

Anoplius lictor, sp. n.
Length 10 mm . $\quad$.
Agrees in size and coloration of the wings and body with A. ardescens, but may readily be separated from it since the third cubital cellule, instead of being almost equal in length with the second, is scarcely half its length.

Front and vertex sparsely covered with long fuscous hair, the lower orbits and clypeus thickly with silvery pubescence. Eyes parallel; the hinder ocelli separated from the eyes by double the distance they are from each other. Aper of clypeus transverse, its sides broadly rounded. Base of mandibles covered with greyish pubescence and with longish hair. Palpi black, the apical joints covered with white pubescence. Thorax pruinose. Pronotum large, its apex with oblique sides. Metanotum with a gradually rounded slope; the pubescence is much thicker on the apex. Wings uniformly fuscous hyaline, with a slight violaccous tint ; the first cubital cellule in front fully twice the length of the third; the first and third transverse cubital nervures roundly curved; the second straight, oblique; the first recurrent is received near the base of the apical third, the second shortly beyond the middle. Legs pruinose; the lower tooth of the claws shorter, thicker, and blunter than the upper. Abdomen pruinose, densely at the apex.

## Anoplius tyres, sp. 1.

Black; the wings fuscous-violaccous, paler on the lower part of the radial, in the cubital cellules, and at the base of the hind wings; the second cubital cellule is nearly twice the length of the third in front, behind not much more than half its length. of.

Length 11 mm .
Lyes obliquely converging above. Front and vertex slightly shining, sparsely covered with black hairs ; there is a furrow below the ocelli and a deeper one above the anteunr. Apex of clypeus distinctly margined, depressed; its sides broadly rounded. Thorax alutaceous; the metanotum thickly covered with a white pile; its apex oblique, broadly rounded above. Legs pruinose, their spines long, stout. The first transverse cubital nervure is obliquely bent at the top, the second straight, oblique, the third roundly curved; both the recurent neryures are received shortly beyond the middle.

## Anoplius fortinatus, sp. n.

Length 11 mm .
Similar in coloration to A. tyres, but is not so stoutly built; may be known from it by the first transverse cubital nervure being roundly, not obliquely curved at the top, by the second cubital cellule in front being more than twice the length of the third, by the front not having two furrows, and by the median segment being more gradually rounded on the apical half.

Front and vertex with a few long hairs, the face and clypeus thickly covered with silvery pubescence. Sides of clypeus rounded. Median segment with a gradually rounded slope on the apex, on the end of which are two deep fover. Wings fuscous with a violaceous tinge, paler at the base and below the stigma. The second cubital cellule behind is not much more than half the length of the third; first transverse cubital nervure roundly curved, the second oblique; the recurrent nervures are received shortly beyond the middle; the subdiscoidal nervure is obliquely turned upwards at the base. Abdomen pruinose.

## Anoplius delphus, sp. n.

Black; the basal four joints of the antennæ rufous; the inner and outer orbits, apex of clypeus, and middle of mandibles ferruginous yellow, the yellow line on the hinder orbits extending on to the vertex near to the hinder ocelli; a line on the pronotum behind, the lower side of the propleuræ, and a mark, broader than long, with straight sides, on the apex of the mesonotum, fulvous yellow; a line, narrowed on the inner side, on the sides of the second segment at the base, a broader, uninterrupted one on the third, and a still broader one on the fifth and sixth, yellow. Legs pruinose, the apical half of the fore femora below and of the four hinder entirely, the base of the front tibiee, the four hinder (except at the base and apex), and the basal two thirds of the basal joints of the four hinder tarsi, red ; the calcaria white; the tibial and tarsal spines red. Wings smoky hyaline, the apex from the sccond transverse cubital nervure dark smoky.

Length 11 mm .
Head smooth. Eycs converging above; the hind ocelli are separated from each other by a distinctly greater distance than they are from the eyes. Aper of clypens semicireular : there is a narrow furrow above the antemm; the vertex
sparsely covered with long fuscous, the orbits and clypens with silvery, pubescence. Thorax sparsely covered with longish black hair and, more sparsely, with a greenish pile. Median segment with a gradually rounded slope. The second cubital cellule at the top is twice the length of the third, at the bottom the space bounded by the first transverse cubital and the first recurrent nervures is as long as the lower side of the third cubital cellule; the first recurrent nervure is received shortly beyond the basal third of the cellule, the second shortly beyond the middle.

The of has only the third to fifth joints red beneath, the third is slightly shorter than the fourth, and the yellow liue on the outer orbits is narrower.

## Anoplius addendus, sp. n.

Length 10 mm . $\mathrm{\delta}^{2}$.
This species so closely resembles $P$. delphas that it might be expected to be its $\delta$; it may, however, be readily separated from it by the vertex being wider at the top through the eyes not converging so much there; there is consequently a wider space between the hinder ocelli and the eyes; the apex of the median segment has an oblique, not a rounded, slope; the first recurrent nervure is received at the base of the basal third, not near the middle, the second is received nearer the middle, the top of the third transverse cubital nervure is not obliquely angled, and the four hinder tarsi are entirely black.

Antenuæ stout, tapering a little towards the apex, as long as the head and thorax united; the scape thickly covered with long white hair; the third, fourth, and fifth joints rufous beneath; the third and fourth joints are equal in length. Head smooth and shining; the clypeus thickly covered with silvery pubescence, the front and vertex with fuscous hair. Eyes not converging above; the ocelli separated from them by the same distance they are from each other. Apex of clypeus transverse, its sides rounded; labrum large, triangularly incised in the middle. Mandibles reddish in the middle; the palpi testaccous, black at the base. Thorax pruinose, shining, smooth; the edge of the pronotum broadly behind and a mark, broader than long, on the apex of the mesonotum rufo-testaceous; the base of the pronotum with a broad band of reddish-bronzy pubescence ; the apex of the median segment has an oblique slope and is thickly covered with pale golden, mixed with bronzy, pubescence. Legs black; the knees and the tarsi rufous, as
is also the base of the front tarsi; the spines and calearia are rufous; the base of the fore tarsi incised. Wing; hyaline ; the apex and the radial and cubital cellules smoky ; the secoud cubital cellule at the top is only a little longer than the third; the first transverse cubital nervure is roundly curved, the other two are straight, oblique; the first recurrent nervure is received shortly beyond the middle, the second near the base of the basal third. Abdomen pruinose; the base of the sccond and third segments distinctly, the fourth and fifth indistinctly, and the whole of the sixth, reddish fulvous ; the last veatral segment is roundly raised in the middle and has an oblique depression on either side of the middle near the apex.

## Anoplius funebranus, sp. n.

Black; the face, checks, and clypeus thickly covered with silvery pubescence, the front and vertex sparsely with long black hair. Wings uniformly fuscous-violaceous, the apical nervures fuscous ; abdomen shining, pruinose. ㅇ.

## Length 14 mm .

Eyes distinctly converging above. Middle of clypeus transverse, the sides rounded. Mandibles rufous before the apex; the palpi black, thickly covered with white pubescence. Thoras pruinose ; the sides of pronotum oblique behind ; the median segment has a gradually rounded slope. The fovea on propleure is long, dcep, pyriform. The first cubital cellule at the top is, if anything, longer than the second; the first transverse cubital nervure is obliquely curved in front, the second straight, oblique, the thicd slightly curved; the first recurrent nervure is received at the base of the apical fourth, the second shortly before the middle.

## Anoplius lanatus, sp. n.

Black, densely prumose, the apex of the pronotum with a pale yellow band, the apex of the abdomen white. Legs (espocially the underside of the coxa and trochanters) thickly covered with silvery pubescence; the apex of the hind femora and the hinder tibie, except at the apex, dark rufous. Wings hyaline, the apex from the end of the stigma smoky. ${ }^{\text {on }}$.

Length almost 8 mm .
Antenne short, thick, the basal joints rufous below; the scape pallid yellow below and covered with white hair. Front and vertex covered with long fuscous hair, the inner

Amn. \& Mag. N. Hist. Ser. 7. Vol. xv.
orbits, face, and clypeus thickly covered with silwery pile. An indistinct furrow on the middle of the front; the apex of clypeus slightly roundly incised; labrum pilose, its apex rounded. Mandibular teeth rufous. Apical joints of palpi testaceous, darker above. Postscutellum thickly covered with long pale hair. Base of median segment pruinose, the lase in the middle with a semicircular depression; its apex obliqucly rounded and thickly covered all over with long woolly hair. Abdomen densely pruinose, slaty grey. First and scond transverse cubital nervures roundly curved ; the third has the upper half straight, oblique ; the second cubital cellule in front is about one third of the length of the third, below not much shorter than it ; the first recurrent nervure is received at the base of the apical third, the sccond in the middle of the cellule.

## Salius fluctuatus, sp. n.

Black, densely covered with golden pubescence ; the basal three joints of the antennee entirely, and the fourth and fifth beneath, ferruginous; legs rufo-fulvous; the cose and trochanters black; densely covered with golden pile; the tips of the tarsi and the apices of their basal joints black. Wings hyaline, with a slight, but distinct, fulvous tint; the stigma and nervures pallid yellow ; the second cubital cellule in front slightly longer than the first; the first transverse cubital nervure straight, obliquely bent at the top, the others roundly curved outwardly; both the recurrent nervures are received before the middle of the cellule. $\delta$.

Length 14 mm .
Claws with one median tooth. Front and vertex sparsely covered with long fuscous hair. Clypeus fulvous, as seen through the golden pile; its apex almost transverse, the sides of the middle part very slightly dilated; laterally it is oblique. Maudibles and palpi fulvous yellow; the teeth piccous. Hinder ocelli separated from the eyes by double the distance they are from each other. Apex of pronotum rounded. Scutellums roundly convex. Median segment with a gradually rounded slope ; alutaccous, not transversely striated, and indistinctly furrowed down the middle. 'Tegulae rufons.

Allied to the Ceylonese S. crimitus.

> Salius Fiederici, sp. n.

Length 17 mm . $\delta^{7}$. Belongs to the section with the claws bidentate, and in

Bingham's table comes into " $b$. Wings fuscous or fuscous black, with a purple effulgence," and nearést to " $c$. The entire abdomen ferruginous red, only the extreme base narrowly black," represented by S. Smithii, Bing., = fervida, Sm., which is very different, it having the head and thorax black.

Reddish brown; the anterior legs reddish yellow; the four hind coxre largely black on the imner side; the basal joints of the hind tarsi slightly black at the base. Base of abdomen black; the apices of the middle segments broadly infuscated; the apical thickly covered with loug stiff black hair; the apex of the penultimate segment depressed and armed with a stout, curved, claw-like tooth, which is broadly black at the apex. Wings dark brownish, with a distinct violaceous effulgence, the base with a yellowish tinge; the first recurrent nervure is received close to the second transverse cubital, the sccond shortly beyond the basal third of the cellule. Antemue dark ferruginous; the scape thickly covered with a pale down. Face and clypeus thickly covered with bright golden down ; the sides of clypeus oblique, the middle transverse. Apex of mandibles black. Front and vertex opaque, granular, sparsely covered with long black hair ; the front furrowed. Apex of pronotum rounded at the apex. Scutellum not much raised ; the postscutellum large, pyramidal, narrowed on the top, the sides behind margined. Middle of metanotum black, depressed, the apex mith an oblique slope; on the basal three fourths are some transverse striæ. Pleural sutures black, crenulated. In front of the hind conæ is a large deep depression, bordered by a stout, somerhat triangular keel.

## Salius satumalis, sp. n.

Black; the anteanre (ercept the apical five joints), head, pronotum, base of mesonotum, apex of femora, tibix, and tarsi ferruginous; the apex of the tarsi black; wings violaceous. $\delta$.

Length 17 mm .
Head ferruginous, the occiput broadly in the centre, the greater part of the vertex and the front broadly in the middle, black; thickly covered with depressed golden pile, the front and vertex sparsely with long black hair. Apex of clypeus almost transverse; in the centre below the antennæ is a raised triangular space, bordered by shallow furrows. Labrum fringed with long golden hair. Apex of mandibles black. The pronotum above is bright ferruginous, the
mesonotum and base of scutellum dark brown and thickly covered with depressed golden pile. Sides of pronotum roundly projecting, its centre furrowed, narrowly below, broadly abore. Scutellum raised, flat on the top. Postscutellum tuberculate, narrowed towards the top, which rises near to the summit of the scutellum; the apices of both are thickly covered with long black hairs. Median segment deep velvety black, transversely striated, sparsely covered with long fuscous hair; the base behind the spiracles tuberculate. Tegule ferruginous. Abdomen deep black: the apical segments thickly covered with long black hair.

This species has the scutellum tuberculate as in S. zelotypus, Bing., but is very distinct otherwise ; in coloration it agrees closely with S. peregrinus, Sm., but that has the pronotum rounded at the base and not tuberculate laterally. The basal tooth of the claw is stout, bluntly rounded at the apex, and shorter than the apical.

## Salius tempestivus, sp. n.

Black, densely covered with pale golden pubescence ; legs hlack, all the femora (except at the apex and the base of the anterior), the four posterior tibice (except narrowly at the apex), and the apex of the front tibie narrowly, ferruginous. Wings fuscous-violaceous, the stigma and nervures black; the base from the transverse basal nervure almost hyaline; the second cubital cellule is slightly, but distinctly, shorter than the third; the first transverse cubital nervure is straight, oblique, its top obliquely angled; the first recurrent nervure is received shortly beyond, the second at the apex of the basal third of the cellule, the transverse median widely separated from the basal. Abdomen pruinose; the pygidial area smooth; its basal half obscurely keeled in the middle ; its sides densely fringed with long fuscous hair. $\circ$.

Length 17 mm .
Antennæ black, bare. Head densely covered with depressed pale golden pubescence, which hides the sculpture. The eyes converge slightly above; the hind ocelli are separated from the eyes by a slightly greater distance than they are from each other. Apex of clypeus smooth, shining, bare, depressed ; the sides slightly, roundly, obliquely curved. Apical half of mandibles rufous; the palpi black, densely covered with white pile. Median segment irregularly, transversely striated. Mesosternum smooth, the furrow narrow, the apex with a transverse keel.

## Salius pracursor, sp. n.

Length 12 mm . 우.
Belongs to Bingham's section "A. Tarsal claws bidentate. a. Wings some shade of fulvous yellow. $a^{\prime}$. Head and thorax black," in which it will form a new section "Abdomen ferruginous." It has a great resemblance to Pseudagenia pulchrifrons, Cam.

Basal six joints of antenne rufo-fulvous; the eighth to tenth black above, dark rufous below, the rest entirely black. Head black, densely covered with golden pile, the clypeus with a more rufous tinge, its middle at the apex with a short tooth; labrum piceous, the apex waved. Mandibles rufous yellow, the apex deep black; the base with a down and some long golden hairs. Palpi yellowish. Thorax densely covered with golden pile, which in fresh examples hides the black colour; the prothorax rufous, a semicircular black mark on the base above, and the middle of the pronotum is black, its lower part with golden pubescence. The median segment with a gradually rounded slope and no furrow ; in addition to the golden pile it is covered rather thickly with long fuscous hair. Propleure dilated above, divided into two beyond the middle by a furrow; in the middle is a narrow oblique furrow. Wings yellowish hyaline, the apex with a faint fuscous cloud; the stigma dark testaceous; the first cubital cellule at the top and bottom slightly, but distinctly, shorter than the third. Legs rufo-fulvous; the coxre black at the base above, the anterior with a distinct yellowish tinge ; the extreme base of the second joint of tarsi and the following black. Abdomen dark ferruginous; the base and apex of the basal segment, the secund segment broadly, and the base of the third irregularly black.

I have referred this species to the section with bidentate claws; but practically there are three teeth, there being a small tooth behind the two larger ones.

The species described in this paper are in the collection of Mr. G. A. James Rothney.
LXII.-Rhynchotal Notes.-XXXII. By W. L. Distant.

> Fam. Cicadidæ (continued).

## Subfam. Tibicininet.

## Division Hyantiaria.

In this division the lateral margins of the pronotum are oblique, not dilated; the abdomen is broad and robust, its dorsal surface contrally obtusely longitudinally ridged, its lateral areas obliquely depressed on each side, its apex narrowed; the tympana are completely exposed, the tympanal coverings being entirely absent; the opercula in the male are short, transverse, not extending beyond the base of abdomen ; the metastemum is centrally globosely elevated and posteriorly terminates in two spinous prolongations placed between the posterior cose ; the anterior femora are spined beneath ; the tegmina and wings are hyaline and usually more or less maculate.

At present the Hyantiaria comprises three Neotropical genera.

## Synopsis of Genera.

A. Posterior pronotal angles dilated.
a. Head with the front long and prominent; longer than vertex.
b. Basal cell of tegmina scarcely longer than broad .... Quesuda.
aa. Head with the front not prominent, much shorter than vertex.
bb. Basal cell of tegmina considerably longer than broad. Mura.
13. Posterior pronotal angles not dilated.
aaa. Head with the front not prominent, a little shorter than vertex.
$b b b$. Basal cell of tegmina a little longer than broad.... Iryantia.
Quesada, gen. nov.
Body broad and robust; head (including eyes) about as wide as base of mesonotum and about as long as pronotum without its posterior margin, front broad and prominent, longer than vertex ; pronotum about as long as mesonotum, its lateral margins oblique, the posterior angles moderately dilated; mesonotum a little convex ; abdomen short, broad, very little longer, sometimes only as long as space between apex of head and base of cruciform clevation, its apex more or less attenuated; tympanal orifices entirely exposed, tympanal flaps altogether absent; abdomen beneath a little
convex to lateral margins, which are flat and at richt angles to disk; opercula in male very small, situate widely apart, and not extending beyond base of abdomen; anterior femora spined beneath; rostrum reaching hase of posterior cosar; metasternum centrally elevated, the process posteriorly triangularly produced between the posterior coxar ; tegmina and wings hyaline, the first long, somewhat narrow, greatest breadth not quite one third of length, venation normal, apical areas eight, basal cell almost as broad as long.

Type, Q. gigas, Oliv. (Cicada).

## Genus Mura.

Mura, Dist. Biol. Centr,-Amer., Rhynch. Hom. i. p. 143 (1905).
'l'ype, M. elegantula, Dist.

## Genus Hyantia.

Hyantic, Stål, Hem. Afr. iv. p. 2 (1866).
Type, H. honesta, Walk. (Cyclochila).

## Division Tettigadesaria.

Lateral margins of the pronotum dilated and usually medially angulate; head varying in breadth and size; tympana completely exposed, the tympanal coverings entirely absent; tegmina and wings either hyaline or semiopaque.

This division is primarily founded on the character of the dilated pronotal margins, and holds a similar position in the Tibicininæ as the division Polyneuraria does in the Cicadinæ and the division Zammararia in the Gæaninæ.

## Synopsis of Genera.

A. Lateral margins of pronotum dilated and medially angulate.
a. Head (including eyes) narrower than base of mesonotum.
b. Space between pronotal dilatations less than width of abdomen.
c. Basal cell of tegmina distinctly longer than broad; tegmina and wings hyaline

Collina.
$l b$. Space between pronotal dilatations considerably wider than breadth of abdomen.
cc. Basal cell of tegmina slightly longer than broad; Orapa.
aa. Head (including eyes) as wide as base of mesonotum.
$b b b$. Space between pronotal dilatations equal to greatest width of abdomen.
$c c c$. Basal cell of tegmina twice as long as broad .. $D a z a$,
B. Lateral margins of pronotum dilated, but not medially angulate.

d. Head (including eyes) about as wide as base of meso-

        notum, its margins moderately convex, the front
    
        scarcely projecting, and about as long as vertex at
    
        area of ocelli
    
    Tetligades.
    dd. Head (including eyes) much wider than base of

    mesonotum, its margins sinuately oblique, the front
    
        strongly projecting, and longer than vertex at area
    
        of ocelli
    
    Chonosia.
    Genus Coldina.
Collinn, Dist. Biol. Centr.-Amer., Rhynch. Hom. i. p. 142 (1905).
'Jype, C. Biolleyi, Dist. (Odopoca).

## Oraps, gen nov.

Head (including eyes) about two thirds the widh of base of mesonotum, its length about equal to space between eyes, front shorter than vertex; pronotum almost as long as mesonotum, its lateral margins ampliated and medially angulate ; abdemen in male short, not longer than space between apex of head and base of cruciform elevation; tympanal orifices completely exposed; opercula in male short, transverse, not quite reaching base of abdomen; rostrum passing posterior coxa; posterior tibixe finely spined on apical half; tegmina and wings semiopaque, the first with eight apical areas and with the basal cell very slightly longer than broad; wings with six apical areas.

Type, O. numa, Dist. (Pycna).
In describing what proves to be the type of this genus I stated that I based my diagnosis on a single female specimen only, which I had kept in my possession for some years, hoping to receive an example of the male. This I have now seen, which enables me to recognize it from its tympanal characters as representing a new genus of the subfamily 'Tibicinine.

## Daza, gen. nov.

Head (including eyes) about as wide as base of mesonotum, in length as long as pronotum (excluding posterior margin), front broad but narrow, not prominent, inserted somewhat deeply in vertex; pronotum shorter than mesonotum, its lateral margins ampliate and medially angulate; mesonotum a little convex; abdomen broad, robust, longer than space between apex of head and base of cruciform elevation; tympanal orifices entirely exposed, tympanal flaps altogether
absent ; abdomen beneath with the disk moderately convex, the lateral margins distinct and slightly oblique; opercula in male small, transverse, well separated internally, not extending beyond base of abdomen, between them there is a flat, transverse, metasternal process ; disk of metastemum elevated, posteriorly triangularly produced between the posterior coxæ; rostrum reaching the posterior coxe ; anterior femora spined beneath; tegmina and wings hyaline, venation normal, basal cell of tegmina much longer than broad.
'Type, D. montezuma, Walk. (Zammara).

## Genus Tettigades.

Tettigades, Amy. \& Serv. Hist. Hém. p. 469 (1843).
Type, T. chilensis, Amy. \& Serv.

## Chonosia, gen. nov.

Head (including eyes) much wider than base of mesonotum, its lateral margins obliquely sinuate, the front strongly projecting and longer than vertex at area of ocelli; pronotum only slightly longer than head, its lateral margins dilated but not angulate, posteriorly oblique; abdomen short, not quite so long as space between apex of head and base of cruciform elevation ; tympana completely exposed, tympanal coverings entirely absent; opercula in male moderately well developed, but not extending beyond the basal segment of abdomen; anterior femora spined beneath; tegmina and wings semihyaline, tegmina more than twice as broad as long; venation similar to that in genus Tettigades.
'Type, C. crassipennis, Walk. (Fidicina).

## Division Huechysaria.

Tegmina and wings opaque or semiopaque; lateral margins of the pronotum neither ampliate nor dentate; abdomen moderately robust, but not transverse, longer than space between apex of head and base of cruciform elevation; tympana completely exposed, tympanal coverings entirely absent; tegmina with the apical areas variable in number, either eight or ten, or variably fluctuating between those numbers.

## Synopsis of Genera.

A. Head with the face longitudinally sulcate.
$\alpha$. Head (including oyes) not so wide as base of mesonotum.

## Genus Graptotettix.

Graptotettix, Stål, ILem. Afr. iv. p. 4 (1866) ; Berl. ent. Zeit. x. p. 170 (1866).

Type, G. guttatus, Stål.

## Graptotettix rubromaculatus, sp. n.

Body black; front of head and face, a large oblique spot on each lateral area of mesonotum, a central longitudinal fascia to abdomen above and the segmental margins, and the abdomen beneath sanguineous, the last with central segmental and lateral segmental piceous spots, apex black; tegmina shining piceous, wings shining fuscous; head (including cyes) not so wide as base of mesonotum, its length a little more than that of pronotum ; mesonotum (including cruciform elevation) longer than pronotum; tegmina with ten apical areas.

Long., excl. tegm., ठ 26 mm .; exp. tegm. 60 mm .
Hab. North Celebes; Toli-Toli (Brit. Mus.).

## Parvittya, gen. nov.

Head (including eyes) not quite so wide as base of mesonotum, shorter than pronotum, the front slightly produced and concavely excavate, the face centrally prominently longitudinally sulcate for about half its length; pronotum almost as long as mesonotum (including cruciform elevation), its anterior angles rounded, lateral margins sublaminate and nearly straight, posterior lateral angles moderately produced; abdomen subglobose, dorsally ridged and posteriorly attenuated; tympanal orifices entitely exposed, tympanal thaps
altogether absent; anterior femora spined bencath; rostrum just passing the intermediate coxa; opercula in male short, transverse, not passing base of abdomen; tegmina semiopaque, with ten apical areas, the basal cell longer than broad.

Type, P. samara, Dist.

## Parvittya samara, sp. n.

Head and pronotum black, greyishly pilose; mesonotum ochraccous, with two central anterior obconical spots, a broad sublateral fascia on each side, and two small rounded spots in front of the basal cruciform elevation, black; cruciform elevation, abdomen above and beneath, opercula, and lateral margins and apical half of face, ochraceous; head beneath, sternum, and legs black, ochraceously pilose; abdomen beneath with small lateral segmental piceous spots; tegmina fuscous brown, venation piceous, its basal area with longitudinal pale fuscous streaks; wings shining pale fuscous.

Long., excl. tegm., ठ 24 mm .; exp. tegm. 63 mm .
Hab. Philippines : Samar (Brit. Mus.).

## Genus Huechys.

Huechys, Amy. \& Serv. Hist. Hém, p. 464 (1843).
Type, H. sanguinea, De Geer (Cicada).

## Genus Scieroptera.

Scierontera, Stầl, Hem. Afr. iv. p. 4 (1866); Berl. ent. Zeit. £. p. 169 (1866).
Type, S. splendidula, Fabr. (Tettigonia).

## Division Carinetaria.

In this division the pronotum is distinctly narrowed anteriorly, never longer than the mesonotum, sometimes much shorter; the lateral pronotal margins are oblique, not ampliate ; the body is more or less robust, narrowed towards head and apex of abdomen, which is sometimes very short; tegmina and wings hyaline, the first in a few cases semiopaque, but usually clear, and frequently unspotted.

The Carinetaria are found in both hemispheres.

## Synopsis of Genera.

A. Head (including eyes) more or less narrower than base of mesonotum ; front about as long or a little longer than vertex.
a. Pronotum considerably shorter than mesonotum.
b. Greatest width of tegmina about one third their length.
c. Abdomen about as long as space between apex of head and base of cruciform elevation ....
B. Head (including eyes) a little narrower than base of mesonotum ; front about as lonor as vertex.
aa. Pronctum not much more than half the length of mesonotum, including basal cruciform elevation.
bb. Greatest width of tegmina less than one third of their length.
cc. Abdomen very short, shorter than pronotum and mesonotum together, including basal cruciform elevation.

Karenia*.
C. IIead (including eyes) as wide as base of mesonotum; vertex a little longer than front.
aaa. Pronotum about as long as mesonotum.
bbb. Greatest width of tegmina little more than half their length

Carineta.

Herrera.
D. Head (including eyes) about half the width of base of mesonutum; vertex a little longer than fiont.
aaaa. Pronotum about as long as mesonotum, including cruciform elevation.
$l u b b$. Greatest width of tegmina a little more than one third their length .

Tympanistria.

## Genus Carineta.

Carincta, Amy. \& Serv. Hist. Hém. p. 48: (1843).
'Iype, C. formosa, Germ. (Cicxdx).

## Carineta boliviana, sp. n.

Body above and beneath fuscous brown, somewhat thickly greyishly pilose; face, a spot between face and cyes, and the femora pale castaneous; anterior femora beneath, tibix, and tarsi dark castaneous; coxe, trochanters, extreme apices of femora, and bases of tibiæ pale ochraceous ; pronotum with a small spot at centre of inner edge of posterior margin and two short, discal, diverging fasciæ, picoous; mesonotum with two central, piccously margined, obconical spots, a transverse spot in front of cruciform elevation, with a short curved spot on each side, piccous; tegmina and wings hyaline, with a

* Another character of this gemus is found in the venation of the tegmina, the bases of the radial area and the lower ulnar area being contignous at lower apical angle of basal cell.
bronzy tint, the venation brownish ochraceons, tegmina with the outer margins very broadly and wings with the outer margins less broadly fuscous; costal membrane of tegmina reddish brown; rostrum almost reaching posterior coxe; opercula in male short, narrow, transverse, not completely covering the cavities; face profoundly longitudinally suleat".

Long., excl. tegm., す $25-2 \mathrm{~s}$ mm.; exp. tegm. $73-81 \mathrm{~mm}$.
Hab. Polivia: St. Paulo (P. O. Simons) and Toungas de la Paz (Brit. Mus.).

By the outer fuscons shadings of the tegmina and wings this species is allied to C.formosa, Germ.

## Carineta illustris, sp. n.

Body and legs umber-brown; head with a large spot on each side of front, the area of the ocelli, and a spot on each lateral margin of vertex, black; pronotum with a broad central discal fascia, widened anteriorly and attenuated posteriorly, where it is connected with a central, transverse, curved, linear fascia, and the lateral margins black; mesonotum with four black-margined obconical spots, the outermost largest, and a lanceolate spot in front of cruciform elevation, black; abdomen above with a subobsolete, central, longitudinal, pale fascia, and with a prominent patch of grey pile on each basal lateral area; sternum thickly greyishly pilose ; face ochraceous, with two central longitudinal black fasciax; a spot at inner margins of eyes, a subapical annulation to anterior femora, intermediate and posterior femora (excluding apices), bases and apices of anterior and intermediate tibix, posterior tibire (excluding base), the tarsi, and apex of rostrum, shining. piceous; tegmina and wings glossy hyaline, the venation umber-brown, tegmina with the costal membrane and a basal patch extending to nearly middle of radial area and occupying the whole of lower ulnar area, and wings with a basal patch which does not reach the middle of radial area and is broadly continued along the margins of anal area, rich deep umberbrown; transverse veins at bases of first and second ulnar areas darkly infuscate, the colour linearly continued across third ulnar area; rostrum reaching the posterior coxæ; head (including eyes) much narrower than base of mesonotum ; abdomen in male as long as space between apex of head and base of cruciform elevation.

Long., excl. tegm., ठ 22 mm . ; exp. tegm. 68 mm .
ILab. Amazons; Iquitos (Stockholm Mus.).

## Carineta peruviana, sp.n.

ㅇ. Body above olivaceous green; ocelli carmine-red; mesonotum with two black-margined obconical spots on anterior margin; lateral margins of metanotum narrowly du!l ochraceous; body beneath and legs pale virescent ; apex of rostrum and the tarsi more or less piceous; spines to anterior femora and posterior tibir fuscous; tegmina and wings hyaline, venation mostly fuscous; tegmina unspotted, the costal membrane pale olivaceous; head (including eyes) much narrower than base of mesonotum, the front about as long as vertex ; pronotum shorter than mesonotum ; greatest width of tegmina about one third their length ; face globose, with a pronounced, very narrow, central, longitudinal sulcation; margins of head, sternum, and legs thickly, somewhat longly, greyishly pilose; abdomen above and beneath a little more shortly and darkly pilose; rostrum just passing the posterior cosæ.

Long., excl. tegm., if 20 mm . ; exp. tegm. 64 mm . Hab. Peru: Chandramayo (Brit. Mus.).

## Herrera, gen. nov.

Head (including eyes) as wide as base of mesonotum, vertex a little longer than front; pronotum about as long as mesonotum, its lateral margins slightly convex, its posterior angles moderately dilated ; abdomen short, about as long as space between apex of head and base of cruciform elevation, tympana completely exposed ; opercula in male small, narrow, transverse, well separated internally; metasternum posteriorly lobately produced from between the posterior cosa; rostrum about reaching the posterior coxe; anterior femora strongly and longly spined beneath, spines apparently three in number; tegmina and wings hyaline; tegmina broad, their greatest width little more than half their length, apical areas eight; wings with six apical areas.
'Jype, II. marginella, Walk. (Cicada).

## Genus Karenia.

Kiarenia, Dist. Ann. Mus. Civ. Genoa, (2a) vi. 1. 458 (1888).
'Type, K. ravida, Dist.

## Genus Tyapanistria.

Tympunistria, Stal, Ann. Soc. Ent. Fr. (4) i. p. 619 (1861),
Type, T. villosa, 'rabr. (Tettigonia).
LXIII.-On some new Japanese Mammals presentert to the British Museum by Mr. R. Gordon Smith. By Olipfield 'Thonas, F.R.S.
The: National Mnseum owes to the kindness of Mr. R. Gordon Smith an interesting collection of small mammals obtained by him in Japan. The majority are from Kobe, but he has also sent a number collected at Misaki, near Yokohama, by a Japanese, Mr. H. Tsuchida.

Most of the species are, of course, described in Temminck and Schlegel's 'Fauna Japonica,' but the following' seem to represent new species or subspecies, and include a vole which, although allied to the red-backed voles (Evotomys), is so distinct that I have had to make a new subgenus for it. It forms, therefore, a most interesting discovery.

## Mogera wogura kobece, subsp. n.

Similar in colour and other characters to typical 11. wogura, but markedly larger.

Dimensions of the type (measured on a spirit-specimen) :-
Head and body 143 mm . ; tail 20 ; hind foot, s. u. 21, c. u. 24 ; fore foot, length (c. u.) 26, breadth 20.

Skull: greatest length 39 ; basal length 34 ; greatest breadth 18.7 ; front of camine to back of $n^{3} 14 \cdot 7$; front of lower cariniform premolar to back of $m_{3} 12 \cdot 8$.

Hab. Kobe, Hondo. Altitude about 60 m .
T'ype. Adult female. B.M. no. 82. 7. 27. 12. Collected 2nd June, 1875, during the cruise of H.M.S. 'Challenger.' Five specimens examined.

While the fine series of the ordinary Japanese mole, M. wogura, from Misaki, near Yokohama, sent home by Mr. Gordon Smith are all very uniform in size (skulls $34-35 \mathrm{~mm}$. ; hind foot, s. u., about 18 mm. ), the four he has sent from Kobe are all markedly larger, and it is evident that we have here to do with two local forms, though they will probably prove to pass one into another in the intermediate districts.

N'o typical locality is given in 'Temminck's original description of Talpa wogura*, but an example sent in 1843 from the Leyden Museum as representing that form agrees in size with the Yokohama race, and I have therefore taken that as the typical one. The original figure of the skull is 35 mm . in length.

[^50]'The 'Challenger' also obtained three specimens of true wogura from Yokohama, besides the example of $M . w$. kobece which I have selected as the type.

Although much larger than true M. wogura, this mole falls far short of the large form from Tladivostok named by Dr. Nehring M. robusta*.

## Petaurista leucogenys and its subspecies.

Mr. Gordon Smith has sent several specimens of the large Japanese flying-squirrel, and I have carefully examined these and the specimens already in the Museum collection.

The original locality of Temminck's Pteromys leucogenys was the mountains of Figo ( $=\mathrm{Hig}$ ) and Fiuga, in the islant of Kiusiu, so that specimens sent from Nagasaki, in the same island, may be provisionally treated as typical.

These are very dark above, with their under surface white or neally white, not or scarcely washed with buffy, their lips with but little greyish white on them, a well-marked blackish patch below the eye and another below the ear, the characteristic light cheek-patch greyish and not sharply contrasted.

From this Kiusiu animal there may be distinguished the following three subspecies:-
P.l. nikkonis, subsp. n.

Fur particularly long and tail bushy. General colour paler, more greyish brown or drab. Under surface white. Muzzle whitish. Below eye greyish brown. Light cheekpatches snowy white, very prominent.

Nikko, central mountainous region of Hondo.
P. l. oreas, subsp. n.

Colour above rich brown, warmer than in the Kiusiu form, and suffused with rufous on the head. Under surface washed with buffy. Patch below cye dark rufous, like forehead. Light cheek-patch dull greyish, inconspicuous, washed with buffy.

Wakayama, southern peninsula of Hondo.

$$
\text { P.l. tos } x \text {, subsp. n. }
$$

Colour above an intermediate brown. Hairs of under suface slaty at base, washed with buffy terminally. Lips whitish. Patch below eye greyish brown, not blackish,

$$
\text { * SB. Ges, nat. Fr. Berl. 1801, p. } 90
$$

succeeded behind by a fairly prominent light cheek-patch, and a dull fulvous one below and behind the ear. Hinder end of nasals squarely truncated.

Tosa, island of Sikoku.
Detailed descriptions of the new forms:-

## Petaurista leucogenys niklonis.

Fur very long, soft, and thick; hairs of back $50-60 \mathrm{~mm}$. in length, the underfur about $40-45$. General colour above comparatively pale, a greyish drab, rather paler than Ridgway's "drab." Individually the longer hairs are greyish basally, with a broad whitish or buffy whitish subterminal band and a fine black tip; the abundant underfur slaty, with about 5 mm . at the tip clay-colour. Laterally the hairs are shorter and the colour becomes more buffy brownish; a broad patch at the end of the patagial cartilage deep ochraceous buff. Under surface either pure white or faintly washed with buffy; no slaty bases to the hairs; a small blackish spot on the chin. Head coloured above like back or a little more buffy, becoming greyish on the nose and whitish round the mouth; cheeks below eyes broccoli-brown; light check-patch very conspicuous, pure white, most of the hairs white to their roots, extending up on to the crown in front of the ears and downwards nearly to meet the white of the throat. Ears surrounded by a buffy area, with scarcely a trace of a black patch at their posterior bases. Forearms dark grey, little mixed with the buffy rings on the longer hairs; hands dark brown. Hind limbs with the dull buffy of the sides extending on to the middle of the metatarsus, its sides and the digits brownish black. Thail short, thick, very bushy, its breadth across the outstretched hairs about 150 mm .; in colour above and below it is of about the same greyish drab as the back.

Skull as in typical leucogenys, the nasals similarly projecting backwards behind the premaxillary processes.

Measurements of the type:-
Head and body 420 mm . ; tail 280 ; hind foot (s. u.) 67.
Skull: greatest length 68.5 ; basilar length 54 ; nasals, length 23; length of upper tooth series without anterior premolar 14.5 .

Hab. Nikko, Central Hondo.
Type. Male. B.M. no. 5. 1. 4. 50. Original number 31. Collected by H. Ogawa, and presented by R. Gordon Smith, Esq. Six specimens examined.

Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.

A young specimen sent by Mr. Maries to the Museum in 1880 lived in captivity from May to August 1879, when it died. It has well developed the peculiar greyness of the back, which cannot therefore be a mark of the winter coat.

Besides one example of the normal colour, a beautiful semialbinistic specimen of a creamy buffy tone was obtained from Mr. Alan Owston in 1900.

## Petaurista leucogenys oreas.

General colour dark, between " vandyke-brown" and bistre, the subterminal rings on the hairs dull buffy; outer part of parachute black, sparsely lined with buffy, the forearms and hands deep black; patch at end of patagial cartilage dark bufty. Hairs of under surface of body dull whitish tipped with buffy, slightly plumbeous at their bases, those of underside of patagium bright buffy throughout except on a patch just behind the carpus, where they are black. Head on muzzle and crown more rufous than back, near "burnt umber." Lips and light cheek-patch dull greyish, little conspicuous, the hairs slaty basally, greyish white terminally. Area below eye dull reddish brown, continuous with the rufous, which passes downwards on to the sides and front of the neck. Chin with a black spot. Upper surface of feet black, with a slight trace of buffy tipping on the centre of the metatarsus. 'Tail long, not unusually broad, breadth actoss outstretched hairs about 125 mm . ; its general colour dull cinnamon, the hairs slaty at base.

Skull with its nasals as in true leucogenys.
Dimensions of the type (measured in skin) : -
Head and body 450 mm . ; tail 380 ; hind foot (s. u.) 73 ; ear 29.

Skull: length of nasals 25 , of tooth-row without $p^{3} 14 \cdot 5$.
Hab. Wakayama, Southern Peninsula of Hondo.
Type. Female. B.M. no. 3. 5. 18. 1. Collected and presented by R. Gordon Smith, Esq.

## Petaurista leucogenys tosce.

General colour above intermediate between the dark leucogenys and the light nikkonis, about matching Ridgway's "hair-brown," subterminal bands on hairs crean-buff; ends of underfur drab-brown. Under surface dingy whitish, the hairs slaty at their bases and washed with bufty terminally. Head brown, not reddish, the top of the muzzle inclined to buffy. Lips and light cheek-patch greyish white, the hairs slaty at base, the cheek-patch not extending up on to the
crown and not very conspicuous. Area below eye broccolibrown, not blackish. Forearms and hands dark brown, a small patch of buffy-tipped hairs on the metacarpus. Hind feet only blackish along the edges and on the digits, the metatarsal hairs being largely tipped with dull buffy. Tail fairly similar to the body, but rather more tinged with claycolour.

Skull distinguished from that of the other forms by the nasals being abruptly and squarely truncated behind at a level with the tips of the premaxillary processes.

Dimensions of the type (measured in the flesh) :-
Head and body 382 mm. ; tail 280 ; hind foot 66.
Skull : greatest length 66 ; basilar length 51.7 ; length of nasals 23 ; upper tooth-row without $p^{3} 14 \cdot 6$.

IIab. Tosa, island of Sikoku. Alt. 300 m .
Type. Female. B.M. no. 5. 3. 3. 17. Collected 4th December, 1904, and presented by R. Gordon Smith, Esq. 'Two specimens.

## Micromys geisha, sp. n.

A delicate species, about equal in size to one of the smaller forms of Mus sylvaticus, though with more the build and look of a large harvest-mouse.

Size small, form slender. Fur soft and fine, without spines, hair of back about 6 mm . in length. Gencral colour above pale reddish brown, rather warmer and redder than Ridgway's "wood-brown," the head and forehead slightly paler than the rump. Under surface white, sharply detined laterally, the basal two thirds of the hairs dark slaty. Ears rather short, pale brown, with a fine white edging. Outer side of upper arms and hips reddish grey; immer sides, wrists, hands, and feet white. Soles wholly naked, last foot-pad elongated ; fifth hind toe ( $s . u_{0}$ ) reaching nearly to the end of the first phalanx of the fourth. Tail of medium length, thinly haired, coarsely scaled, the scales not alternated, but forming distinct rings, averaging about twelve to the centimetre ; both scales and hairs brown above and white beneath, but the contrast not conspicuous. Nammæ apparently $2-2=8$, but this numeration is not absolutely certain.

Skull very smooth, light, and delicate, rounded and without ridges, the supraorbital elges hardly squared even in the oldest example. Anteorbital plate straight-eiged in front, scarcely projected forwards in advance of the upper bridge. Palatal foramina of medium length, not extending backwards to the front of $m^{1}$. Mesopterygoid fossa wide and rounded in front, narrowing posteriorly. Bulle normad. Molar's small, $33 \%$
of normal structure, a well-marked antero-external secondary cusp on $m^{2}$, as well as the usual large antero-internal.

Dimensions of the type:-
Head and body (c.) 85 mm . ; tail 95 ; hind foot (s.u.) 19 ; ear 125.

Skull: greatest length 24 ; basilar length 17.5 ; zygomatic breadth 12 ; masals 8 ; interorbital breadth 3.7 ; breadth of brain-case 11 ; palate length 10.4 ; diastema $6 \cdot 5$; palatal foramina $4.7 \times 1^{\circ} 7$; length of upper molar series 3.4 .

Hab. Kobe, Hondo. Alt. $300-400 \mathrm{~m}$.
Type. Male. B. M. no. 5. 3. 3. 37. Collected May 1904. Presented by R. Gordon Smith, Esq.

This pretty little mouse is quite unlike any Eastern Asian species with which I am acquainted. Mus urgenteus, T'emm., whose description might have been thought to apply to it, is a larger animal, with a hind foot of 22 mm ., and many differences in the detailed measurements of the skull, e.g. interorbital constriction 4.9 mm ., palatal foramen 5.8 .

With regard to the use of the generic name Micromys for this animal, I have come to the conclusion that the correct and natural division of the European species of "Mus" published by Hensel in $1856^{*}$, and supportel by Forsyth Major $\dagger$ in 1884, should be followed, and that while Mus vattus, norvegicus, and musculus should remain in Mus, the others should be placed in a separate genus, for which the name Micromys is available.

In this genus the posterior laming of the first and second upper molars have each an additional internal cusp beyond the number present in Mus; so that, counting along the inner side of the tooth-row, there are three cusps on the first molar and three on the second, while in Mus the posterior lamina is not continued inwards beyond the centre, and there are therefore only two imer cusps on each of the two teeth.

The following species, with their respective near allies, show this character:-

Micromys sylvaticus, L.

- speciosus, 'Temm. (Type of genus $\ddagger$. )
- minutus, Pall. (Typinus, Dant. \& Alst.
- agrarius, Pall.
- Harti, Thos.
* Zeitschr. deutsch. geol. Gesellsch. 1856, p. 281.
+ Atti Soc. Tosc. Proc. Verb. iv. p. 129 (1884).
$\ddagger$ Dehne, 1841 .

In no Oriental or Australian species are the molars of this character, but among the African forms, although in the great majority as in typical Mus, those of Mus arborarius, Peters, and M. rutilans, Peters, are almost precisely as in Micromys and appear to indicate a real relationship to that genus.

In view of the immense number of species of Jus known and the difficulty of dividing them into natural groups, it is of great value to be able to separate off any section of them by essential characters, however slight these may appear to be.

Evotomys (Phaulomys) Smithii, subgen. et sp. nn.
Phaclomys *, subgen. nov.
External proportions and other characters as in Evotomys, although the colour tends more towards brown than the usual red of Evotomys.

Skull with the smooth non-angular brain-case characteristic of Evotomys; zygomata more widely splayed; posterior palate typical ; bullæ unusually small.

Teeth not rooted in the only specimen, which is fully adult; therefore if rooted at all they must only become so very late in life, as in Craseomys. Base of second upper molar in a distinct capsule at the bottom of the orbital fossa and that of the last lower molar similarly encapsuled on the inner side of the incisor-root, both as in Craseomys and Microtus, not as in Evotomys. Molars very weak and narrow (breadth of $m^{2}$ barely more than half its length, 0.8 mm . as against $1 \cdot 5$ ), the few closed triangles not or scarcely broader than long. General structure of teeth showing an exaggeration of the Evotomys characters of rounded cement-areas and coalescence of opposite spaces (see figure, p. 494). Last upper molar more simple than in Evotomys, its second and third spaces coalesced into one. B low the anterior molar is also remarkably simple, and in all three teeth the outer re-entrant angles are nearly as deep as the inner.

This interesting form adds another to the considerable number of aberrant Asiatic voles, and, as with Antheliomys and Eothenomys, the exact value that should be given to it is by no means clear. While it has the rounded skull, roundangled teeth, and external form of true Evotomys, it has the encapsuled $m^{2}$ and $m_{3}$ of Craseomys, Antheliomys, and normal
voles, while its molar pattern and narrow teeth are peculiar to itself. On the whole, it may best be called a subgenus of Erotomys until such time as the whole group is again revised, when it will very probably receive with others the dignity of full generic rank.

The species may be described as follows :-
Size about as in Evotomys glarcolus. Fur soft and loose; hairs of back about 10 mm . in length. General colour above a light brown, not far from "russet" of Ridgway, without the warmer and more reddish tone of true Evotomys. Sides and rump not conspicuously or abruptly greyer than the back. Under surface cream-buff, not sharply detined, and mixed with the slaty of the hair-bases; throat grey. Ears about as long as the fur, well-haired, brown. Upper surface of hands and feet dull greyish; soles hairy from the heel to the pads. 'lail about two thirds of the trunk-length, well-haired, the terminal pencil about 3 mm . in length; dark brown above, pale greyish below.

Skull as described above.

Evotomys (Phavlomys) Smithii. Upper and lower molars, right side. $\times 10$.

Teeth (sce figure). - First and second upper molars with the usual five and four cement-spaces respectively. Third molar with the normal anterior space, and the second and third half opposite to each other and combined in one; then follows a teminal $Y$, the antero-external corner of it almost separated into a distinct space; this tooth has three prominent angles and one additional indistinct one on each side. Anterior
lower molar with only four simple spaces, one in front of the others, the anterior representing the front triangle, the second the normal second and third, and the third the normal fourth and fifth triangles, here opposite and coalesced with each other. Outer and inner re-entrant andes about equally deep, as they are in the second m lar, which has the usual Eeotomys pattern. Last molar with its outer re-entrants much deeper than usual, nearly as deep as the inner ones.

Dimensions of the type (measured in the flesh by Mr. Gordon Smith) :-

Head and body 79 mm . ; tail 54 ; hind foot 17.5 ; ear 10 .
Skull : greatest length $24 \cdot 3$; basilar length $20 \cdot 7$; zygomatic breadth $14 \cdot 6$; nasals $7 \cdot 2 \times 3 \cdot 3$; interorbital breadth $3 \cdot 9$; breadth of brain-case 10.3 ; height of brain-case from basion 6.5 ; palate length 11 ; diastema 6.8 ; palatal foramina $4 \cdot 2 \times 1 \cdot 4$; antero-posterior length of bullæ 5 ; length of upper molar series (crowns) 5 , of $m^{3} 1 \cdot 6$.

Hab. Kobe, Hondo. Alt. 650 m.
Type. Male. B.M. no. 5. 3. 3. 49. Collected 24th February, 1904. One specimen only.
"Under pine-trees, in bamboo-grass."-R. G. S.
This vole, representing a new subgenus, forms a most interesting addition to the known fauna of Japan, and I have much pleasure in connecting its donor's name with it.
LXIV.-Notes on Eastern Heterocera, with Descriptions of new Genera and Species. By Coloncl Charles Siwinhoe, M.A., F.L.S., \&c.

## Family Syntomidæ.

Euchromia plagosa, nov.
우. Frons white, tegulæ orange ; patagia and band at base of abdomen greyish yellow, next segment black, the third metallic blue with a white spot in the middle, the next two orange, intersected by a black line, the last two black with blue bands in them: fore wings with some metallicblue marks at the base, both wings with similar marks at the ends of the cells; spots white, a short longitudinal mark below the cell near the base, two spots in and below middle of cell (the latter the larger), two between veins 3 and 5 , and one below vein 6 : hind wings with a short subcostal white
streak near the base and a discal band divided by the veins into three white spots.

Expanse of wings $1_{10}^{8}$ inch.
Neu Pommern, Kinigunang; one example.
Nearest to E. cyantis, Meyrick, Trans. Ent. Soc. 1889, p. 457 , from N. Guinea.

## Euchromia shortlandica, nov.

ㅇ. Black ; frons and first segment of abdomen greyish yellow, the latter with a blue spot in the middle; head and thorax with metallic-blue marks; second and third segments of abdomen metallic blue with black bands, the remaining segments crimson with black bands: fore wings with some blue marks at the base; both wings with blue marks at the ends of the cells, white semihyaline spots as in E. creusa, Linn.

Expanse of wings $1_{10}^{9}$ inch.
Shortland Island, Salomons.

## Euchromia salomonis, nov.

q. Head and body very similar to the preceding species, but the first segment of the abdomen has two brown patches, and is without the metallic-blue middle spot; the spots on the fore wings are larger, there is a white streak below the upper discal spot, the lower middle spot joins the subbasal streak and runs in broadly nearly to the base; on the hind wings the basal hyaline band is divided into three spots by the veins as usual, but the upper one is much the lougest and the outer discal band is very large.

Expanse of wings 2 inches.
Isabel Island, Salomons.

## Euchromia collaris, nov.

ठ. Black; frons white and coxæ white; tegulæ scarletorange ; head and thorax black with metallic-blue markings; abdomen with the first segment half black and half scarletorange, next two metallic blue with black bands, the fourth black, and the remainder crimson with black bands : fore wing with blue markings at the base, a wedge-shaped hyaline white spot in the middle of the cell, a thicker and larger spot below it, the upper portion of it running thickly to near the base of the wing; four longitudinal spots on the disk, two between veins 3 and 5, a narrow one below these which nearly reaches the lower middle spot, and the usual
spot below vein 6: hind wings with the basal and discal bands joined together, making nearly the whole wing hyaline, leaving a square black spot at the end of the cell, and an outer marginal black band which is thickened at the apex and at the anal angle of the wing.

Expanse of wings 2 inches.
Shortland Island, Salomons.

## Family Lithosiidæ.

## Phaosia brumea, nov.

o ㅇ. Head, thorax, and abdomen dark brown, amal tuft of abdomen yellow: fore wings with the ground-colour pinkish grey, covered with brown suffusion in parts and several brown longitudinal streaks, the most prominent being two short streaks following each other beyond the cell, one at the apex and another on the costa before the apex: hind wings uniform brown, yellowish at the tips, no markings. Underside of a uniform pale slaty brown: fore wings with short pale streak on the costa beyond the middle and another along the hinder margin : body below white; legs smeared with white, tarsi with white rings.

Expanse of wings, of $\frac{8}{10}$, of 1 inch.
ठ, Sarawak, Borneo (Moore Coll.). In B. M.
q, Padang, W. Sumatra.

## Genus Ctexane, nov.*

Proboscis fully developed; palpi porrect, extending about the length of head, the sccond joint thickly scated; antemure of male bipectinate, the apical third ciliated; hind tibize with two pairs of spurs: fore wing short and broad, vein 2 strongly curved from angle of cell, 3 from before angle, 4 and 5 from angle, 6 from below uper angle, 7, 8, 9, and 10 stalked, 10 from beyond 7 ; 11 from cell, oblique: hind wings with veins 3 and 4 stalked, 5 from well above angle, 6 and 7 stalked, 8 from middle of cell.

## Ctenane labuana, nov.

ठ. Head, thorax, and abdomen grevish white tinged with brown; palpi blackish except at the tips: fore wings grey-white irrorated with brown and blackish; a subbasal black point below costa, antemedial black points below costa and above vein 1 ; a diffused medial fuscous-brown band,

[^51]attenuated at the middle and broadening to costa and hinder margin ; an ill-defined postmedial line, oblique from costa to vein 4 , then incurved, with black points on it below costa and above and below vein 2 ; onter area diffused with brown, except at apex, and with traces of a sinuous submarginal line: hind wings very pale fuscous.

Expanse of wings $\frac{1}{2}$ inch.
Labuan, Borneo.

## Family Limacodidæ.

Ceratonema fusca, nov.
it. Head and collar dark brown ; body and fore wings pale brown with a slight pinkish tinge; abdomen with brown segmental bands: fore wings with the central upper area suffused with dark brown, forming a large suffused patch; a transverse, recurved, simuous brown line beyond the middle, rumning through the outer limit of the brown suffusion; a submarginal paler line with indistinct pale brown streaks rumning from it to the outer margin: hind wings pale greyish brown without markings. Underside of a uniform pale greyish brown without markings, but with a blackishbrown suffused space in the central upper area of the fore wings.

Expanse of wings ${ }_{10}^{3}$ inch.
Khasia Hills.
There are two examples from the Khasia Hills in the B. M., Limacod drawer no. lō, unnamed.

## Family Lasiocampidæ.

Crostogastria pruni.
Bombyr pruni, Linn. Syst. Nat. i. p. 498 (1758).
Odonestis pruni, Kirby, Cat. Moths, p. 811 (1892).
1 of, Khasia Hills.
1 of, Jaintia Hills.
Differ in no way from the European insect, except in being rather duller in colour.

## Arguda vita.

Odonestis rita, Moore, Cat. Lep. E. I. C. ii. p. 424, pl. xii. a, fig. 4 (1859).
$1 \delta, 1$ ㅇ, Calcutta, October 1889.
The type came from Java. These examples stood in my collection as $O$. bheroba, Moore, but I have now examined
them with the types in the B. M.: the latter is a very different insect with straight transverse lines and seems to be rery rare ; the type is in Coll. Staudinger and the co-type in the B. M. My Calcutta examples of vita do not differ in any way from the Javan type.

## Stenophyllodes khasiana, nov.

ठ. Palpi much shorter than in S. sikkima, Moore, colour of a nearly uniform brownish fawn with a tinge of pink; branches of antemne pale blackish; collar pale and somewhat ochreous; body without markings: fore wings pale towards outer margins and less well clothed; hind wings slightly darker than the fore wings; both crossed by numerous indistinct waved lines slightly darker than the ground-colour ; a black dot at the end of cell of fore wings. Underside paler, the fore wings more pink tinged and without markings; the hind wings with two short brown lines running down from the costa near the base, and three indistinct sinuous lines across the disk.

Expanse of wings 2 inches.
Khasia Hills.
A smaller insect than S. siklima, with the outer margin more deeply crenulate.

## Family Trifidæ. <br> Euplexia fasciata.

Xylophasia fasciata, Leech, Trans. Ent. Soc. 1900, p. 68.
Khasia Hills; common.
The type from Western China is in the B. M. and is identical with the Assam examples.

## Euplexia repetita.

Apamea repetita, Butler, Cist. Ent. iii. p. 133 (1835).
Khasia Hills ; one example.
The type came from Yokohama.

## Radinacra albosignata.

Caradrina albosignata, Oberth. Etud. d'Ent. r. p. 72, pl. iv. fig. 1 (1880).

Khasia Hills, $1 \delta$.
: The type came from Amurland; there are several examples in the B. MI. from Central and Western China; it is closely
allied to R. lineusa, Moore, a common Indian insect, but the transverse lines on the fore wings are closer together and the reniform is of a different nature.

Family Acontiidæ.
Metachrostis brunneiplaga, nor.
子 $子$. Palpi, head, and thorax dark pinkish brown, palpi with the last joint pale: fore wings pale pinkish brown, a hromn patch at the base with nearly upright outer margin, a large brown costa! patch extending from beyond the middle nearly to the apex, some brown spots on the costa; indications of a medial double line, also of three sinuous lines below the patch, and three large pale brown spots on the outer margin ; marginal line very thin and interrupted by the reins; cilia with a pale brown interline: hind wings pale pinkish brown, paler than the fore wings, with an indistinct pale brown marginal line.

Expanse of wings $\frac{7}{10}$ inch.
Khasia Hills ; many examples.
Not unlike M. brimnea, Leech, Trans. Ent. Soc. 1900, p. 157, from Central China, but that form has no basal band.

Motina cqualis.
Motina aqualis, Walker, xxvii. 12 (1863).
Khasia Hills.
The type from Sarawak, Borneo, is in the B. M.

## Family Quadrifidæ.

## Blasticorhinus rivulosa.

Thermesia rivulosa, Walk. xxxiii. 1060 (1865).
Acantholipes quadripuncta, Swiwhoe, Ann. \& Mag. Nat. Mist. (7) ix. p. 423 (1892).

The type from Moulmein is in the B. M. The type of quadripuncta, also in the B. M., is from Palawan. I have it also from the Nilgiri Hills, and there are examples in the B. M. from Ceylon and from Java.

## Family Focillidæ. <br> Avitta surrigens.

Oroba survigens, Walker, Journ. Linn. Soc., Zool. vii. p. 81 (1864).
Audaman Islands (Bingham).
The type from Sarawak is in Mus. Oxon.; in Cat. Het.

Mus. Oxon. ii. p. 194, I made it a synonym of $A$. subsignetns, Walker, but I wrongly identified that species; the fore wings are rounder, it is paler in colour, the transverse markings are entirely absent, and there is a large round blackish spot at the end of each cell. I have subsignens from Sumba, Perak, Queensland, Andamans, Bombay, and the Nilgiris; I have surrigens from Gilolo, and it is in Mus. Oxon. from Sarawak, Flores, Sula, and Aru.

## Genus Bethantha, Walker.

Bethantha, Walker, xxxiii. 982 (1865).
Seneratia, Moore, Lep. Ceylon, iii. p. 202 (1885).

## Bethantha bisignata.

Bothantha bisignata, Walker, xxxiii. 983.
C'typansa boccunidia, Butler, Ann. it Mag. Nat. Hist. (5) x. p. 231 (1882).

Ceylon, Nilgiri Hills.
Walker's type from Timor is in Mus. Oxon., also an example from Ceylon; the type of bocanidia, from Duke of York Island, is in the B. M. I have it in my collection from Saparea, New Guinea, Kina Balu, Mouklek Mommtains (Siam), Nilgiri Hil s, and Ceylon. It is not mentioned in Hampson's 'Moths of India.'

## Adrapsa atratalis, nov.

of. Dark brownish black, very uniform in colour: fore wings with a white dot at the end of the cell ; transverse lines white, sinuous, antemedial, postmedial, and submarginal; the first bends inwards close to the hinder margin, the second bends outwards, the submarginal line ruus from the costa into the inner side of a very large subapical, pure white, almost square patch, and is continued in a row of white dots to the hinder margin; outside the patch on the margin are four pure white lunules, and the black cilia have white spots: hind wings with a medial line which does not reach the e sta, a submarginal row of white dots, and indications of a marginal white line. The underside is paler, having some white suffused scales on the wings: on the fore wings the cell-spot and postmedial line are bordered inwardly with black, and some white suffusion in place of the subapical patch; on the hind wings are three transverse white lines-antemedial, medial, and discal-the first two rather close together, all inwardly bordered with black; both
wings with whitish marginal lunules and white spots on the cilia.

Expanse of wings $1 \frac{9}{10}$ inch.
Khasia Hills. In B. M.
At page 162 of this vol. by mistake I described the female of this insect as the female of $A$. curiosalis, but I have found both sexes of this form from the Khasia IIills in the B. M., the antenne of the male differing from the antenne of curiosalis, with large scale-tooth on outer side just beyond basal joint, the shaft then curved, with small scale-tufts on the joints and fascicles of cilia; at one fourth from base the shaft is dilated into a large knot.

There is also an example in the B. M. from Western China (Leech Coll.).

## Family Hypenidæ.

## Bomolocha obductalis.

Hypena obductalis, Wallier, xvi. 56 (1858).
Bomolocha obductalis, Swinh. Cat. Het. Mus. Oxon. ii. p. 212 (1900).
Hypena vestita, Moore, Lep. Ceylon, iii. p. 221, pl. clxxvi. fig. 10 (1885).

Khasia Hills ; fairly common.
The type, marked "India," is in Mus. Oxon, the type of vestita from Ceylon is in the B. M.; they camot be separated. It is also in the B. M. from Sikkim. The allied form eductalis, Hmpsn., the type of which from Sikkim is in Coll. Elwes, is the commonest form in the Khasia Hills: flexuosa, Moore, which Sir George Hampson puts as a synonym of obductalis, is in my opinion quite distinct; I have it from Simla, Darjiling, and Kulu.

## Genus Anepa, nov.

Palpi oblique ; third joint smooth, a little more than half the length of the second: fore wing long and narrow, excavated from apex to vein 4 , where there is a rather prominent angle; antennæ ciliated and abdomen with dorsal tufts, as in the genus Hypena, but the shape of the wings and upturned palpi clearly separate it from that genus and all its subdivisions.

Type, oayduta, Hmpsin. (Hypena oxydata), Journ. Bombay N. H. Soc. xi. (4) p. 707 (1898).

## Anepa doda.

Hyppena doda, Swinhoe, Ann. \& Mag. Nat. Mist. (7) ix. p. 180 (1902).
Khasia Hills.
The type from Goping, Perak, is in the B. M.; also examples from Penang, Formosa, and Sikkim.

## Family Geometridæ.

Medasina leledaria, nov.
ठ. With the ground-colour ochreous grey, irrorated with olive-brown atoms, and spots, bands, and markings all olivebrown ; antennæ, palpi, frons, head, and thorax dark olivebrown; abdomen paler: wings with a rather large spot at the end of each cell ; subbasal, medial, and discal transverse bands, all more or less duplex and incomplete, showing best towards the costal and hinder margins; the last band curved outwards below the costa and inwards before the hinder margin, and dentated in the middle on both wings ; a submarginal white dentated line and a marginal black crenulated linc. Underside pale grey, nearly white, with darker grey irrorations, blackish cell-spots, and a broad blackish discal band, attenuated hindwards on both wings ; tarsi with white, bands.

Expanse of wings $2_{10}{ }^{1}$ inches.
Khasia Hills.
There is an example from Bhutan in the B. M. in Boarmid drawer no. 127.

## Boarmia properata.

Boarmia properata, Walker, xxi. 376, ठ才 (1860).
Boarmia acaciaria, Hmpsu. (part.), Moths India, iii. p. 264 (1895).
Boarmia cornuria, Swinh. (part.), Cat. Het. Mus. Oxon. ii. p. 290 (1900).

Thyetmyo, Burma.
The type (a male, said to be from North Hindustan) is in the B. M. I have both sexes from Burma and Perak, and find that it is quite distinct from either acaciaria or cornaria; the former has the antennæ of the female almost simple, whereas in the female of properata the autenuæ are strongly pectinated for three fifths the length, as in the male, but the pectinations not so strongly prbescent; it comes under Warren's subgenus Carecomotis (Nov. Zool. iii. p. 402) ; the female of comaria has also pectinated antenne. I have examples from Ceylon and south India; the pectinations are, however, much shorter, and it is smaller and differently coloured.

## Heterabraxas rufonotaria.

Mefabraras rufonotaria, Leech, Ann. \& Mag. Nat. Hist. (6) xix. p. 451 (1897).

## $2 \delta$, Khasia Hills.

The type came from Western China; the markings on the Khasia Hill examples are darker black, otherwise there is no difference.

## Family Thyrididæ.

Rhodoneur'a candidatalis, nov.
ot. Frons white; head and thorax brown, the latter white hindwards; abdomen and wings white, the former with indistinct chocolate-grey bands: fore wings with the costal space smeared with pale chocolate-brown, with many striations of the same colour, these striations extending to the base of the wing and on the basal half of the hinder margin; two duplex discal lines of the same colour, intertwined, near each other on the costa near the apex, gradually separating to the hinder margin, where the first is a little beyond the middle and the other near the angle: hind wings with three similar duplex lines, the first near the base, the second across the middle, and the third across the disk. Underside same as upperside, the lines more pronounced.

Expanse of wings $1_{10}^{2}$ inch.
Silchar, Cachar.

## Rhodoneura mollicellalis, nov.

б. Palpi, frons, head, and collar bright chestnut-red; body and wings of a unifurm ochreous fawn-colour ; abdomen with the penultimate segment white, the ultimate black, the anal tuft white: both wings eveuly irrorated and striated with minute pale black marks; a pale subapical mark on the costa of fore wings, with two pure white spots obliquely below it, these black dots in a line near the outer margin above vein 5 ; some black dots in the centre and near outer margin of hind wings ; cilia of both wings dull chestnutred. Underside paler and more ochreous, the white costal subapical spots on the fore wings conflucnt, forming a little white patch, the striations and irrorations more sparse, but both wings have many larger black dots; legs white beneath.

Expanse of wings $1_{3} \frac{3}{0}$ inch.
Khasia Hills; a fiue series.
The three black dots above vein 5 near the outer margin of the fore wings are not always constant-in one example there are only two and in another they are all absent.

## Rhodoneura turbatalis, nov.

ठ. Palpi, frons, head, and collar chestnut-red ; body and wings pale pinkish grey ; abdomen with a brown dorsal band and a prominent blackish-brown spot on the penultimate segment, ultimate segment and anal tuft concolorous with the body: wings rather sparsely covered with brown even striations; fore wings with the outer half suffused with brown, except for a small space on the hinder margin beyond the middle; hind wings with a broad suffused brown medial band; a triangular ochreous-white patch on the costa near the apex, including two small brown costal spots; a black dot abore vein 5 near the outer margin; marginal line brown; cilia on fore wings ochreous, with brown patches; cilia on the hind wings ochreous brown, without patches. Underside as above, but the ground-colour is nearly white and there is no band on the hind wings; legs concolorous with the body, without markings.

Expanse of wings $1_{10}^{20}$ inch.
Khasia Hills ; a fine series.
Both the above are allied to $R$. atripunctalis, Walker, from Java, but are quite distinct.

## Family Hydrocampidæ.

## Piletocera chrysorycta.

Semioceros chrysorycta, Merrick, Trans. Ent. Soc. 1884, p. 320.
Nacoleia contingens, Moore, Lep. Ceylon, iii. p. 273, pl. clxxix. fig. 8 (1885).

Meyrick's type came from Duaringa, Queensland, Moore's from Ceylon: I have it from both localities and also from Sarawak, and I cannot see how they can be separated; they have not a character which is not common to both.

## LXV. - Notes on Subspecies of European Shrews (Sorex and

 Neomys). By G. E. H. Barrett-Hamilton.In continuation of my studies of European and British Mammalia in the British Museum of Natural History I find amongst the shrews two very distinct subspecitic forms, the extremes of which are very clearly marked. The one a water, the other a common shrew, were trapped by Mr. C. G. Danford in the same region in the Southern Carpathians at Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.
altitudes varying from 1500 to 5500 feet. They may be described as follows:-

Sorex araneus carpathicus, subsp. n.
Size.-The collector's measurements indicate an animal slightly smaller, but with relatively longer tail, than S.araneus typicus of Britain.

Colour in winter above from base of tail to occiput nearly black, the face and sometimes the upper surface of the head lighter, gradually becoming brown on the flanks; below, including inner surfaces of all four legs, dirty light yellow or brown, the colour of the upperside encroaching considerably upon the belly. Line of demarcation moderately distinct, rumning on each side from a point between angle of mouth and nose to the shoulders, thence to the thighs and base of the tail, dividing inner and outer surfaces of all four legs to the wrists and ankles. Hidden portions of the hair everywhere blackish slate.

Tail bicoloured, the upper surface near "bistre" ", the lower between "isabella color" and " drab."

Feet between "prout's brown" and " hair-brown."
A single specimen in partial summer coat is near grizzled " mummy-brown" above, below yellower than specimens in winter coat.

Dimensions in millimetres of nine Specimens.

I am unable to distinguish the skull from that of British shrews.

Hab. Hatzeg, Transylvania, Southern Carpathians, at altitudes of 1500-5500 feet.

Type (a female), no. 3. 2. 2. 4 of British Museum Collection, taken at Hatzeg, 30th November, 1902, altitude 5 อ00 feet. Dimensions:-Head and body 64 mm ., tail 46 , hind foot 13 , ear 7.

This is an interesting mountain-form of "saturated"

[^52]coloration, conspicuously darker than British or Scandinavian forms of $S$. araneus, and lacking the markedly tricoloured arrangement prevalent in specimens from the continental plain.

Neomys fodiens naias, subsp. n.
Size.-The collector's measurements indicate an animal of about the same size as the British form, but with slightly longer tail and larger cars and feet.

Colour above near black, sometimes with a tuft of whitish hairs just behind each ear ; below glossy or silvery "crean," sometimes almost white; line of demarcation distinct, its course as in the Sorex described above. Hidden portions of the hairs above "blackish slat"," below lighter and almost approaching " plumbeous."

Tail bicoloured similarly to the body and with inferior " keel" of whitish hairs.

Feet lusky to silvery grey, the inner surfaces darker: soles nearly black, thickly fringed with whitish hairs.

## Dimensions in millimetres of ten Specimens.

| Maximum | Head and |  | Hind foot. | Ear. |
| :---: | :---: | :---: | :---: | :---: |
|  | body. | Tail. |  |  |
|  | 84 | 66 | 20 |  |
| Mean | $77 \cdot 1$ | $60 \cdot 7$ | $18 \cdot 8$ | $6 \cdot 6$ |
| Minimum | 68 | 56 | 18 | 5 |
| Mean of 11 British specimens. | \} 85.4 | $53 \cdot 27$ | $17 \cdot 1$ | $8 \cdot 4$ |

The skull has a basilar length of 18 to 20 mm . ; as compared with skulls of British specimens, the rostral region is somewhat more attenuated and the upper canine somewhat more conspicuous.

Hab. Hatzeg, Transylvania, Southern Carpathians, at altitudes of 1500 to 2000 feet.

Type (a female), no. 3. 11.8. 11 of British Museum Collection, taken at Nechesh Galben, Hatzeg, 3rd November, 1902, altitude 2000 feet. Dimensions:-Head and body 79 mm ., tail 66 , hind foot 19 , ear 7.

This beautiful water-shrew far excels the British form in brilliancy and contrast of coloration. Nearly all the continental water-shrews which I have been able to examine are of more silvery-white tints on the under surface than the British, but the Transylvanian seems to present an extreme of the series.

The specimens in the British Museum indicate that the $34^{*}$
common shrew of the continental plain is subspecifically distinct from the representatives of the species occurring in Britain, Scanlinavia, or in the mountain-ranges of Europe. The latter are dully coloured forms, whereas the shrew of the plain is a large brilliantly tricoloured form, having a band of intermediate colour interposed on the flanks between the colours of the upper and under surfaces. The appropriate subspecific name for the shrew of the plains would appear to be S. tetragonurus, Zimmermann (Geog. Gesch. \&c. ii. p. 383, 1780), while Mr. Miller has bestowed on two mountain forms the subspecific names of alticola (from Switzerland) and euronotus (from the Pyrenean foot-hills) - see Proc. Biol. Soc. Wash., April 25, 1901, pp. 41-45.

Since the dull coloration of the British water-shrew entitles it to subspecific rank, it should be known as Neomys fodiens ciliatus (Sowerby), Brit. Misc. t. xlix. p. 103 (1805).
LXVI.-Notes on European Species of the Subyenus Pitymys (Genus Microtus). By Dr. C. I. Forsyth Major.

## 1. Microtus (Pitymys) duodecimcostatus (Selys).

Arvicola duodecimeostatus, De Selys-Longchamps, Rev. Zool., Année 1839, p. 8 ; id. Etudes de Micromammalogie (Liége, 1839), p. 110, pl. iii. fig. 4 bis.
This species rests on two skeletons, both presenting the anomaly of twelve (instead of thirteen) ribs, which De Selys considered to be a specific character. One of the skeletons is from the neighbourhood of Geneva ("des environs de Genève") ; De Selys had received it from the well-known Geneva palæontologist Professor Pictet de la Rive: the second skeleton, in the Paris Museum, is from the neighbourhood of Montpellier. The former, being the first mentioned in both theabove-quoted papers, must be considered the type of " Arvicola duodecimcostatus."

The specimen from Montpellier was, in 1854, identified by Z. Gerbe as the "Arvicola incertus, Selys," from Southern France, and is therefore a Pitymys. "Il y a, sous tous les rapports, une si parfaite similitude entre la tête osseuse de l'A. incertus et celle du squelette à douze paires de côtes, que le Musćum d’histoire naturelle de Paris tient de M. Olivier, sous le nom de Mus (Arvicola) æconomus, que je n'hésite pas à identifier ce prétendu Mus aconomus
a l'A. incertus; or, comme ce squelette est rapporté par M. de Selys-Lonyehamps à son A. duodecimcostatus, il s'ensuit que cette espèee, dont on ne comnaissait que la charpente osscuse, u'est qu’un 1 . incertus, offrant la singulière anomalic de n'avoir que douze paires de côtes et douze vertèbres dorsales an lieu de treize . . ." *.

The Geneva skeleton agrecing, according to what De Sclys had originally asserted, in every respeet with the one from Montpellier, Gerbe concluded furt her that "-A. incertus" oceurs also in the neighbourhood of Geneva; in a postseriptum to his memoir, however, he states as follows :-" M. de SelysLongehamps, dans une lettre en date du 2 zt juillet dernier, me dit avoir recomnu que le squclette d' $A$. duodecimcostatus qui lui vient de Genève se rapporte à l'A. Baillonii, et n'est par conséquent point semblable, comme il l'avait avancé dans ses Etudes de Micromammalogie, à celui du Muséum d'histoire naturelle de Paris. Dès que cette similitude n'existe pas, il n'y a plus lieu de supposer que le Campagnol incertain doive se trouver dans les environs de Genève" $\dagger$.

What, in 1854, De Selys may have meant by "Arvicola Baillonii" it is difficult to guess, but it does not matter much. Blasius has "Arvicola duodecimcostatus" as a synonym of the Microtus arvalis $\ddagger$, and is herein followed by V. Fatio §.

The upper and side views of the skull of the Geneva skeleton are represented in the figure 4 bis (pl. iii.) of the ' Micromammalogie.' In the great depth of the skull, backward from the rostrum, its longitudinal arching, and the subcylindrical shape of the brain-case it shows so ummistakably the characteristic form of the skull of Microtus "incertus" from Southern France, so well described by Gerbe \|, that we may safely consider the skeleton to be that of a species of Pitymys, either identical with the M. "incertus" as described and figured by Gerbe, or else very nearly related to it; so that the two skeletons of "Arvicola duodecimcostatus" may, after all, be one and the same species.

In Fatio's 'Campagnols du Bassin du Léman' no Pitymys is recorded; in the same writer's 'Faune des Vertébrés de la Suisse' the only Pitymys mentioned from Switzerland is

[^53]the Microtus (Pitymys) Sarii, discovered by Pavesi above Lugano in the Canton Tessin*。

When series of complete specimens of both the Microtus duodecimcostatus and the "Arricola incertus" of Southern France are to hand a direct comparison will be possible. According to Gerbe the habitat of "A. incertus" is the whole of Provence and Languedoc, part of the Roussillon and of the Dauphiné $\dagger$. In the Basses-Alpes, according to the same writer, it is common in the natural meadows with southern exposure $u_{p}$ to a height of almost 2000 metres $\ddagger$. Gerbe does not state in what part of this extensive region the specimen or specimens described by him were obtained.

Concerning the specific name "incertus": even if the Geneva specimen proved to be different specifically from the Southern France form described by Gerbe, the name cannot be retained for the latter unless it could be shown to be identical with a species from the St. Gothard (Switzerland), for which it was originally used by De Selys. At the Sccond Congress of Italian Scientists convened in Turin in Sept. 1840, De Selys declared "Arvicola incertus" to be a species provisionally founded on two specimens from the summit of St. Gothard, which are said to differ from $A$. Savii by larger size, more robust feet, and more yellowish coloration of the skin $\S$. He is more explicit in a communication made at

[^54]Zurich in the following year:-"Anvicola incertus (Selys). Campagnol incertain.-Je signalerai cette espè̀e nouvelle sur un individu du musée de Zurich, pris dans son nid par monsicur le prof. Schinz, près de l'hospice du St. Gothard, à plus de 6000 pieds d'élévation. Elle y avait formé un magasin composé de racines du saule des Alpers. Il ressemble, par ses oreilles excessivement courtes, à l'Arvicola Savii (Selys), espèce qui se troure dans toute l'Italie; mais il est d'un pelage jaunâtre, à peu près comme l'arvalis. Ses pieds à ongles robustes et ses oreilles sont notablement velus, et sa taille est comme celle des grands exemplaires de l'arvalis. Si ce n'est pas une espèce distincte, c'est l'Arricola Savii qu'il faudrait alors inscrire dans la faune helvétique.Monsieur Baillon (d'Abbeville) possède un exemplaire de l'Arvicola incertus, provenant des cnvirons de Toulon. Il est semblable à celui du musée de Zurich " *.

The specimen from the St. Gothard described by De Selys was alluded to by Schinz himself in 1837 as a Microtus arvalis:-"Hypudeus arvalis.-Sie Iegt anf Ebenen und Bergen Magazine an. Schinz fing diese Maus auf der höchsten Höhe des Gotthardtpasses in den ersten Tagen des August.- - Hier legen sie für ihre Grösse beträchtliche Magazine von verschiedenen Wurzelarteu an, welche man im Frühling oft noch in grossen runden Haufen angehäuft finder. Diese Wurzeln, von denen man wenigstens drei Arten unterscheiden kann, sind mit Grashalmen vermischt. Auf dem Gotthardt suchen arme Kinder sie begierig auf und essen diese Wurzeln" $\dagger$.

In his 'Synopsis' Schinz expressly states that this specimen is distinct from his "Hypudeus rufescente fuscus, syn. H. rufo-fuscus, Schinz," discovered by Nager lower down, in the Urserenthal $\ddagger$.

The specinen from the St. Gothard is again mentioned by De Selys as Arvicola incerius in 1843, together with specimens from Saint-Zacharie (Tar) and from Montpellier §. In his writings of the following years the St. Gothard, gradually drops out from the habitat of the "A. incertus," and in 1847 the name Arvicola Baillonii, which had already done service twice and had been twice relegated to synonymy

[^55]—of M.agrestis* and of M. arvalis + ,-is revived for the St. Gothard form $\ddagger$, and, as stated above, in 1854 is applied to the type of $M$. duodecimcostatus.

To sum up: both the specimens on which rests the "Arvicola duodecimcostatus, De Sclys," are to be assigned-the type on the strength of the figured skull, the Montpellier specimen on the authority of Gerbe-to a characteristic group of the subgenus Pitymys, represented by various species from Southern France (also from the Pyrenean Peninsula aud. from Montenegro). If the type specimen of Microtus duodecincostutus is not forthcoming, we must await the rediscovery of this species in the neighbourhood of Geneva before deciding whether it is or is not specifically identical with the one from Montpellier. In any case the name duodecimcostatus (1839) antedates the name incertus (1810), the latter, moreover, referring originally to some specimen from St. Gothard, considered by De Selys to be nearly related to M. Savii, but which from its size seems rather to be some form of the $M$. arvalis group.

## 2. Microtus (Pitymys) lusitanicus (Gerbe).

Arvicola (Microtus) lusitanicus, Z. Gerbe, Rev. Mag. Zool. (3) vii. pp. 44, 46, 47 (1879) ; id. Bull. Soc. Zool. France, v. p. 56 (1850).
There would be some justification for ignoring the above specific name proposed by Gerbe, since, according to his own declaration, the species has not been described, but only "signalée"; moreover, the two characters which were made known, viz. small size of the animal-" taille inférieure it celle de toutes les espèces qui vivent en France" $\$$-and reduced condition of the middle outer triangle of $m^{3}$, apply equally well to two distinct species of the Western Pyrenean Peninsula, the one from (ialicia, the other from Cintra and presumably other parts of Portugal. Sinece the former may or may not occur likewise in the northern districts of Portugal, whereas the skull on which the species M. lusitanicus rests is from Portugal, I adopt this name for a species

[^56]represented in the Natural History Museum by fourten specimens collected at Cintra by Mrs. Mary and Mr. Oldfield Thomas. Mrs. Thomas not only assists her husband during his collecting-trips, but science is further indebted to her for helping in the arrangement of the collections of skills of small mammals in the Natural History Musemm ; I have therefore associated her name with the species from Galicia described further on.

Nicrotus lusitanicus belongs to the same group as M. duodecimcostatus, as revaled by the arched upper contonr of its skull, its deep, subeylindrical brain-ease, the backward shelving of its occipital, its protruding upper incisors, and the absence of closed triangles in $m^{3}$, the middle outer triangle of which is much reduced. The characters of the skull and of the incisors are somewhat less pronounced than in the larger species of the group. Those of $m^{3}$ conversely are very well marked: out of the fourteen specimens only in three is the reduction of the middle triangle not so marked as usual-in one (no. 98.2.2.49) this occurs on both sides, in two (nos. 98. 2. 2. 41 and 47) on the right side only. The fusion of the two middle (outer and inner) triangles, leading to the formation of a transverse loop and consequently to the absence of any closed triangle in this tooth, is constant in all the fourteen specimens.

The development of a supplemental triangle on $\mathrm{m}^{2}$, more rarely on $m^{1}$ also, which is a characteristic feature in adult specimens of several species of the subgenus, is of rather exceptional occurrence in the members of the duodecimcostatus group. Out of the fourteen specimens of the present species only two exhibit this pentamerodont character. In one (no.98.2.2.37) the supplemental triangle is moderately developed on both the $m^{2}$, in the other (no.98.2.2.47) it is more conspicuous and a beginning of a similar development is visible also on the right $m^{2}$.

Coloration.-Above "bistre",*, some specimens approaching more to "broccoli-brown." The bistre-coloured are "smoke-grey" below, with a more or less admixture of "buff" in those approaching to "broccoli-brown" in the upper parts. (All the specimens from Cintra are of a decidedly darker coloration above than that exhibited in another species of the M. duodecimcostatus group from the neighbourhood of Seville. The largest of these, represented by numerous specimens in the Natural History Muscum,

[^57]Collector's Dimensions (in millim.) of the fourteon specimens (nos.98. 2, 2. 37-50), taken in the flesh.

attain the dimensions of $M$. ibericus (Gerbe). Their coloration is above "bistre," with a tinge of "isabella colour," below grey with a strong admixture of "buff.")

Four inguinal mamme (two on each side) and fire footpads on the hind sole were noted in the fresh specimens by the collector.

## 3. Microtus (Pitymys) Thomasi, Barrett-Ham.*

The skull of this large species, from Montencgro, bears little resemblance to that of M. Sarii, and is the very converse of the very low skull of M. subterrancus; it agrees in its general features with the members of the M. duodecimcostatus group, and likewise in the character of the protruding upper incisors. In the pattern of $\mathrm{m}^{3}$ there is a tendency towards formation of closed triangles, and the middle outer triangle, with the exception of one specimen (no. 1), is scarcely reduced. Taking the specimens one by one, $m^{3}$ exhibits the following characters :-

Collector's no. 85, ad. ㅇ. .-No closed triangles ; middle outer triangle scarcely reduced.

Collector's no. 16, ad. ㅇ. --Outer and inner middle triangles almost closed.

Collector's no. 1, ad. $\mathrm{d}^{3}$.-The outer and inner middle triangles are closed on the right side; on the left they are confluent, forming a transverse loop. Middle outer triangle reduced.

Collector's no. 86, young ad. ot - No elosed triangles.

## 4. Microtus (Pitymys) Maria, sp. n.

This oldicate species is represented in the Natural History Museum by seven spirit-specimens (B.M. nos. 94.1.1.16 and 17; 94.3.19.6-8; 95.4.29.4 and 5) from Viilalva, Prov. Lugo, Galicia, presented by the late Dr. V. L. Seoane.

Coloration.-The specimens, which have been nine years in spirit, show in the adult the upper parts of a brown tinged with " raw umber"; the lower parts are of a shining "buff."

Compared with the members of the duodecimeostatus group this form has a narrower, more elongate, rather Hattened, low brain-case; zygomata less spreading; upper incisors not protruding. Apart from its smaller size, the skull resembles that of Nicrotus Surii, exaggerating somewhat the latter's characteristic outline ; the upper contour represents an even straighter line, with more abruptly

[^58]shelving nasals. The lateral palatal grooves are deep in the adult. Third upper molar without any closed triangles and with the middle outer triangle much reduced; this tooth shows therefore the characteristic pattern of the duodecimcostotus group.

Four inguinal mamma.-Five foot-pads on the hind sole.

LXVII. - On the Preorbital Pit in the Skulls of Domestic Horses and Quaggas. By R. I. Рососк, F.L.S., F.Z.S., Superintendent of the Zoological Society's Gardens.
In the 'Annals' for last November (p. 317), when criticising Mr. Lydekker's statements and opinions with regard to the presence of a preorbital pit upon the skulls of horses and quaggas and the systematic value claimed for it, I remarked that its known occurrence in two truc quaggas' skulls would to a certain extent justify a provisional generalisation as to its constancy in that animal, were it not that this pit belongs to the category of characters which are likely to appear sporadically as atavisms and are therefore, from the systematic standpoint, open to suspicion on the score of inconstancy; and I added that "such characters are of
doubtful value as a basis for the formation of natural groups, for functionless vestiges have sefdom much importance in taxonomy." This was written on the assumption of the correctuess of the claim that the depression is the remains or vestige of the much larger pit which, in more arehaide forms, e g. Hippurion, lodged, it is held, a facial gland comparable to that of Cervide. My conclusion as to the systematic value of the character in question was, and still remains, I believe, quite sound, although I do not think the hypothesis that has been put forward as to its significance can be accepted as substantiated by the tacts; and, until we get further evidence on the point, I incline to the view that Sir William Flower was probably right in saying that no trace of the preorbital depression seen in the skull of Hipparion is to be found [in the adults] of any of the existing species of Equidæ.

For the purpose of testing the frequency of the presence of this depression in horses and of ascertaining, if possible, by rough dissection, if any gland be discoverable over the spot, I examined this area of the skull in several horses slaughtered in the Zoological Society's Gardens for food.

My methods of investigation were not precise enough to justity a denial of the existence of a vestige of a gland; but I failed to detect any difference between the subcutaneons tissue overlying the depression when it was present and that overlying the corresponding area of the skull when it was absent. As for the depression itself, it is sometimes present, but more often absent: it exhibits, indced, every gradation between a hollow perceptible to the eye and touch and a perfectly flat bony surface. From this hollow or from the corresponding area of the skull arises a long muscle which passes forwards to supply the upper lip and nose; and I believe that its sole significance is to give an increase of surface for the attachment of muscular fibres. If this be so, variation in the extent to which the depression may be developed is exactly what would be expected.

It is possible, but hardly, I think, probable, that the very large preorbital pit in Hipparion was also an area for muscular attachment. Iis appearance and structure suggest no such function; and there is practically nothing in the formation of the naso-premaxillary region of the skull pointing to the possession by this extinct equine of a larger or more flexible upper lip, requiring an increased muscular supply, than is found in recent members of the family.

On the other hand, a comparison between casts of the skulls of Hipperion and Onohippidium forcibly suggests that
the facial pits in these two genera are homologous structures, despite their diffcrence in position. The pit of Onohippidium is larger even than that of Hipparion and lies higher on the face, in correlation with the extremely elevated fronto-nasal region of the skull. But in both the casts of the skull of the former genus that I have seen there may be noticed, a little below and in front of the orbit, an additional, quite shallow depression, foreibly recalling, both in position and development, the preorbital muscular depression that cxists in some skulls of recent Equidr.

This pit is well developed in the skull of the quagga in the British Museum, and is also shown, as Dr. Forsyth Major has pointed out, in the drawing of a quagga's skitl published by de klainville. From these two data Mr. Lydekker felt justified in concluding that it is a constant characteristic of quaggas' skulls; and, believing in its absence from the skulls of Burchell's Kebras, he went a step further and used the character as a basis for separating specifically the (2uaggas from the Burchell Zebras. This latter opinion was easily refuted by the demonstration of the presence of the pit in a skull of a specimen of Grant's race of Burchell's Zebra: and I am now in a position to state that the conclusion as to the constancy of the occurrence of the pit in quaggas' skulls was also too hastily established; for in the Museum of the Royal College of Surgeons there are skulls of two stallion quaggas, and in neither of them is a trace of the depression perceptible *.

## PROCEEDINGS OF LEARNED SOCIETIES.

## GEOLOGICAL SOCIETY.

January 4th, 1905.-J. E. Marr, Sc.D., F.R.S., President, in the Chair.
The following communication was read:-
'The Marine Beds in the Coal-Measures of North Staffordshire.' By John T. Stobbs, Esq., F.G.S. With Notes on their Palæontology by Wheelton Hind, M.D., B.S., F.R.C.S., F.G.S.

Owing to the disposition of the rocks and other canses, the stratigraphical position of the marine beds can be located with exactness in situ, and a large quantity of material can be obtained for examination. The horizons can be utilized for the identification of coal-seams and for the subdivision of the Coal-Measures, as they are remarkably persistent, and can be frequently traced not only

* I am indebted to Mr. R. II. Burne for the opportunity of examining these two skulls and also casts of the skulls of Hipparion and Onohippidium.
over the North Staffordshire field but in adjacent coalfields. The known horizons at which marine fossils have been obtained are the following, given in descending order :-

> 11. The roof of the Bay or Lady Coal.
> 10. The l'riorsfield Ironstonc-Measures.
> 9. The Speedwell and Nettlebank Bed. \{ Below the Twist or
> 8. The Florence Colliery-Band. $\}$ Gin-Mine Coal.
> 7. Above the Moss Coal.
> (6. The roof of the Moss Cannel or Single 2-foot Coal.
> 5. Above the 7 -foot Banbury Coal.
> t. Reneath the 4 -foot Coal of Cheadle.
> 3. The Knypersley Band.
> 2 . Near the Crabtree Coal (three horizons).
> And also 1. The Weston-Spriak Bed.

A map of the distribution of these beds is given, each one is described in detail, and a list of fossils found from the varions exposures is tabulated. The Speedwell and Nettlebank Bed appears to be the most important marine bed in the coallield; it is remarkably rich in species and individuals, and occurs in the upper portion of the true Coal-Measures. Further, it proves the identity of the Twist coal of the Norton area with the Gin Mine of Longton. Lithologically, the marine beds are undistinguishable from the beds with which they are interstratified; but the fossils are usually in a good state of preservation and not confined to one particular bedding-plane; the individuals are likewise numerous. The marine mollusca are, however, sharply separated from the freshwater forms, and no intermingling occurs. It is remarkable that several of the marine shales immediately succeed the coalseams. A detailed table of the beds in North Staffordshire is given, to show the exact position of the marine beds; and then several of the seams are traced into the Yorkshire, Lancashire, South Staffordshire, and Coalbrookdale fields. This tracing confirms the conclusion that the Hard Bed of Yorkshire is to be correlated with the Bullion coal of Lancashire and the Crabtree coal of North Staffordshire. Again, 'Green's marine bed' at Ashton-under-Lyme coincides with the Cin-Mine horizon of North Staffordshire; and this, again, with the Pennystone of South Staffordshire and Shropshire. Further, the marine beds indicate the approximate identity of the Silkstone, Arley-Mine, and Cockshead seams. A bibliography is appended.

Dr. Hind, in his Notes on the Palæontology, remarks that from the base of the Pendleside Series to the top of the Coal-Measures there is an unbroken succession of beds-at oue time marine, at another estuarine, without unconformity. The two faunas-one with Carbonicola, Anthracomya, and Aaiadites, the other with Pterinopecten papyraceus and cephalopoda-occur in irregular alternations, the two faunas never mingling. The Author procecds to give notes on the occurrence of many of the species, and descriptions of some of them, including examples not hitherto known from Britain and one new to science. A table indicating the distribution of the species throughout the chicf English Coalfields concludes the paper.

## MISCELLANEOUS.

An overlooked Work.
In $18 \% 1$ or 18.2 there was published, by authority of the Lords Commissioners of Her Majesty's Treasury, at Southampton, a work entitled 'Ordnance Surrey of the Peninsula of Sinai. In three parts.' Part I. is a folio of $\mathrm{iv}+323 \mathrm{pp}$. and 20 plates, and contains zoological matter which has apparently been overluoked, or at any rate has not been referred to, in any Record or Catalogue of Zoology that I am acquainted with, viz. :-
"XI. Zoology: Part 1. Notes on the Mammals and Avifauna of the Peninsula." By Cladde W. Wyatr. Pp. 251-262, plates xiv.-xx.
"Part 2. List of the Coleoptera found during the Progress of the Surrey." By G. R. Crotсн. Pp. 263-268.
"Part 3. Notes on Diatomacere." By Edward T. W'ilson. Pp. 269-272.

Thore are other interesting subjects in the work, e.g. "X. Plants of the Peninsula." By Dr. J. D. Hooker.

As regards the Zoology, I am informed by Professor Newton that a list entitled "Notes on the Birds of the Peninsula of Sinai" was published by Mr. Wyatt in 'The Ibis' for 1870 , pp. 1-18. On reference I find that this paper makes no allusion to the author"s larger work on the subject nor to the plates therein.

Mr. Crotch's contribution is a list of 128 species of Coleoptera, of which the following are new:-Saprinus sinaiticus; Pachydema sinaitica, isratitica, and nocturnt: p. 266. P.? sancta; Erodius sinaticus and $\begin{gathered}\text { costatus ; Adesmia Drakii, sinaitica ; T'entyria I'almeri: }\end{gathered}$ p. 267. Sepidium korah, dathan, and abiram; T'ychius sinuiticus; Chrysomela sanguinco-cincta: p. 268.

I have found the types of all these species in Mr. Crotch's collection, now in the University Museum of Zoology, Cambridge.

Mr. Wilson's notes on the Diatomacer do not include any new species.

The titlepage of this work bears date 1869 , but the preface is dated Oct. 31st, 1871, and this Zoology was therefore probably not published till 1872.

A copy of the work was presented to the University Library, Cambridge, by the Rt. Hon. the First Commissioner of H.M. Works; and I am much indebted to our University Librarian, Dr. F. J. H. Jenkinson, for finding it for me, when the only clue I could give him was a reference about Mr. Crotch's types contained in the archives of our Museum. D. Sharf.

University Museum of Zoology, Cambridye, March 22nd, 1905.

## THE ANNALS

## MAGAZINE 0F NATURAL HISTORY.

[SEVENTH SERIES.]

No. 90. JUNE 1905.
LXVIII.-Some Bees of the Genus Melissodes from the Rocky Mountain Region. By T. D. A. Cockerell.
The following table separates a series of comparatively large females, all 12 mm . or more in length :-

Hair on inner side of basal joint of hind tarsi black or almost
1.

Hair on inner side of basal joint of hind tarsi red. 4.

1. Smaller, with more convex, black, very shiny abdomen; hair of labrum pale reddish; middle of thorax above naked; eyes pale greenish grey
glenwoodensis, Ckll.
Larger, with flatter, less conspicuously shining abdomen; pubescence of thorax more ochreous
2. 
3. Hair on labrum pale; thorax hairy, or overlapped with hairs, in middle above; eyes pale reddish ; abdomen conspicuously banded. Mizer, Ckll.
Hair of labrum dark or brownish
4. 
5. Smaller, hair of pleura all light .............
6. Size very large; facial quadrangle not broader than long
blakei, Chll.
chrysothamni, Ckll.
helianthelli, Ckll.*.

* The following characters are also useful:-

Wings strongly yellowish; stigma entirely ferruginous.
Second submarginal cell much broader above than its height.
helianthelli.
Steond submarginal cell much narrower above than its height

Martini.
Wings not strongly or not yellowish; stigma with at least the lower part darkened
all the other species in the table
Ann. 8. Mag. N. IIist. Ser. 7. Vol. xv.
Size smaller; facial quadrangle broader thanlong5.
5. Hair of thorax above bright orange-fulvous . :Hair of thorax above not orange-fulvous;abdominal bands narrow and white; eyespale green. . . . . . . . . . . . . . . . . . . . . . . . . . .6. Ilair on middle abdominal segments white .. thelypodii, Ckll.Martini, Ckll.Hair on middle abdominal segments fulvous . . Heacetti, Ckll.
Melissodes glemwoodensis, sp. n.
q.-Length about 12 mm :

Shining black, with greyish-white pubescence (not at all fulvous or ochraceons) on head and thorax ; middle of thorax nude, without black hair ; flagellum dark, obscurely reddened beneath; hair of apex and venter of abdomen black or sooty ; the abundant scopa on outside of hind tibix and tarsi whitish, with a strong reddish tinge. This is a species of the group of $M$. desponsa, and is very closely allied to M. mysops, Ckll., from which it is distinguished by the shorter abdomen, and particularly by the eyes distinctly diverging above (in mysops they are practically parallel); also by the larger and therefore less numerons punctures of the clypeus, the redder tegulx, and the largely pale hair on the four anterior legs. The hind femora are clothed with black hair in mysops, but with light hair in glemwoodensis. From M. cnici, Rob., the new species differs at once by the conspicuous white abdominal bands, narrow and widely interrupted on the second segment, broader and very narrowly interrupted on the third, and very broad and not or very slightly interrupted on the fourth; it also differs by the more shining surface, the colour of the eyes, \&c.

Hab. Glenwood Springs, Colorado, Sept. 15, 1903, "only a few specimens seen"; collected by Prof. C. P. Gillette.

This is so close to M. mysops that I should be inclined to ascribe the various little differences to variation, were it not for the evidently different set of the eyes. The abdomen appears more globose and convex, but this is no doubt largely due to retraction.

## Melissodes Mizea, sp. n.

## ㅇ. -Length a little over 15 mm .

Black, robust, with a broad and rather flat abdomen ; hair of head and thorax long and rather silky, pale ochreous (quite without black) on vertex, occiput, and thoracic dorsum, white on face, cheeks, and under part of thorax; eyjes pale reddish, becoming grey or blackish posteriorly; head broad,
facial quadrangle broader than long; front and vertex shining; flagellum beyond the first joint deep ferruginous beneath; elypeus densely punctured; labrum densely covered with very pale ochreous hair ; mandibles stout, with a large orange subapical patch; mesothorax shiming, with large well-separated punctures posteriorly, and small closer ones anteriorly; tegule very dark brown. Wings rather dusky, nervures dark; first recurrent nervure entering second sul)marginal cell near the beginning of its last fourlh. Leess black, with the small joints of tarsi mainly ferruginons; pubescence of legs mainly pale, black on immer side of basat joint of middle and hind tarsi, shining more or less orange or reddish on inner side of anterior and middle tibie and anterior tarsi, grey on outer side of anterior tarsi ; seopa of hind legs large, in the type full of orange pollen. Abdomen shining; the first segment with the usual ochreous hair, the second with basal and median hair-bands, the third with a broad band, and the fourth with a broader one, covering its apical margin, but giving way to some black basally ; these abdominal bands all yellowish white; the two apical segments covered with purplish-black hair; hair of venter grey-brown, light at extreme sides. The absence of black hair on vertex and thorax separates it from M. montana, confusu, grindelice, \&c. The black hair on inner side of hind tarsi separates it from M. menuacha, gilensis, \&c.

Hab. Las Vegas, New Mexico, Aug. 11, 1899, at flowers of Grindelia inornata, Greene; collected by Miss S. L. Mize.

## Melissodes blakei, sp. n.

## ㅇ.-Length about 14 mm .

The abdomen narrower, and with much narrower bands, than that of M. Mizece; vertex, occiput, and thoracic dor:sm with very pale ochreous pubescence, without any black; face, cheeks, and under part of thorax with white or nearly white hair ; head broad, facial quadrangle broader than Jong"; eyes pale grey with a faint greenish tinye; flagellum, except at base, deep chestnut-red beneath; labrum covered with pale greyish-brown (as if dirty) hair; mandibles shining, apicall!, rather slender, with an orange subapical streak; posterior middle of mesothorax nude, shining, with large widely separated punctures; middle of scutellum also inude, with smaller, closer punctures; tegulæ piccous, reddish porteriorly. Wings slightly dusky ; first recurrent nervure entering second submarginal cell about or before the beyiming of its lust third. Legs black, the tarsi becoming reddish apically ; hair of legr
mostly pale, but black or dark fuscous on inner side of middle and hind tarsi, shining fulvous on inner side of anterior tarsi; scopa of hind legs abundant, in the type full of orange pollen. Abdomen shining, but not excessively so, with narrow median white hair-bands on segments 2 to 4 , and indications of a second (basal) band on 2 ; the two apical segments with dark fuscous hair; hair of venter dark reddish fuscous. By the colour of the hair on the legs and thorax \&c. this resembles M. Mizere, but it is evidently a distinct species. In addition to the characters cited, the third antemal joint is shorter than that of Nizea. Compared with M. pallidicincta, the abdominal bands of blakei are narrower, the rertex is not so broad, and the black hair on the scutellum is lacking. The insect is considerably larger than M. grindelice, and otherwise different.

Hab. Beulah, New Mexico, end of August (Cockerell).
The name commemorates the Blake ranch, the entomological headquarters at Beulah during several seasons. The width of the abdomen of blakei is 5 mm ., of Mizere nearly 6 . The locality of M. Mizere is in the Upper Austral zone, that of M. blakei in the Canadian zone.

## Melissodes chrysothamni, sp. n.

## ㅇ.-Length almost 18 mm .

Large and robust, black, with pale ochreous pubescence, tinged with fulvous on scutellum and anterior part of mesothorax ; without black on thoracic dorsum or vertex, or with a few black hairs at each extreme side of vertex, above top of eye; hair of labrum, lower part of pleura, base of legs, and ventral surface of thorax generally, black or sooty, perhaps best described as brown-black; hair of venter of abdomen, of middle tarsi and inner side of lind ones black; hair of legs generally dark, but the middle femora, anterior femora behind, and basal half of anterior tibie on outer side have light hair in considerable quantity ; the anterior tibia have dark red hair on inner side ; the copious scopa of the hind legs (in the specimens seen filled with orange pollen) is light. Abdomen dullish, broadened towards the apex; apical margin of first segment rather broadly reddened in one specimen, but not in the other ; first two segments not obviously banded; third and fourth with dull yellowish-white hairbands, that on third inclined to be interrupted, that on fourth very broad and entire; bases of third and fourth segments with black hairs ; the two apical segments with black hair. Eyes silver-grey; facial quadrangle broader than long, but
not very greatly so ; mandibles stout, simple, more or less reddened, the orange streak minute; clypeus densely and confluently punctured; tegula very dark red-brown. Wings moderately dusky; first recurrent nervure joming second submarginal cell about the begimning of its apical fourth; flagellum dark, only slightly reddened beneath. Of the general build and appearance of M. macharanthera, but easily distinguished by the black lers, dark antenne, \&ce. It is also related to M. Smithii (D. T.).

Hab. Embudo, on the Rio Grande, New Mexico, Sept. 26, at flowers of Chrysothamnus, two specimens (Cockerell).
M. comptoides, Rob., also has the pubescence of thorax with no black dorsally, but fuscous or black beneath; it is a much smaller species ( $12-13 \mathrm{~mm}$.) and occurs in Illinois.

## Melissodes helianthelli, sp. n.

ㅇ. -Length almost 18 mm .
Even more robust than M. chrysothamni, the thorax being larger, and the abdomen broader basally; puhescence of head and thorax dense, erect, pale fulvous, quite bright orange-fulcous on vertex (where there is no black) and anterior part of mesothorax, white on face and cheeks, pale orange on labrum and underside of mandibles ; pallid, but by no means white, on lower part of pleura and metathorax ; hind part of mesothoras with a rather small, strongly punctured exposed area, having a few black hairs; scutellum, ersept the margins exposed, dull and densely punctured, this area fringed with coarse black hair; hair of legs pale fulcous, without any black; the pale fulvous scopa of posterior legs very strongly plumose; hair on inner side of tarsi and of hind tibiee bright ferruginous; small joints of tarsi ferruginous. Abdomen dullish; hair on first segment whitish and rathershort, without any black (in M. chrysothamni the hair at the base of the first segment is strongly mixed with black) ; second, third, and fourth segments with the portions overlapped by the segment before covered with dense tomentum, which on the second is white, on the third pale ferruginous, on the fourth dark purplish fuscous; basal part of sccond segment, narrowing medially, with appressed white hair, apical part glittering with microscopic golden hairs ; third and fourth segments with broad white hair-bands, faintly stained with yellowish, that on third more or less failing in the middle, these bands separated from the basal tomentum in each ease by a stripe of dark fuscous; apical segments with the hair reddish chocolate, extreme base of fifth black; venter with dark reddish hair.

Facial quadrangle about square, perhaps a trifle longer than broad ; eyes light yellowish green ; flagellum, except at base, deep red beneath; mandibles stout, with a large orange stripe ; tegule light ferruginous. Wings strongly yellowish on basal half, nervures ferruginous; second submarginal cell wery broad, receiving the first recurrent nervure a considerable distance from its end. Differs from M. comanche, Cresson, by the duller abdomen, with white bands, the light (apricot-coloured) tegulæ, $\& c$. It is a stouter insect than M. macharantherce, and differs in the colour of the eyes (pale bluc-green in of macharantherae), the dark (not red) scape, femora, \&c. ; it is, however, closely allied.

Hab. Mesilla, New Mexico, at flowers of the small sunflower Helianthus ciliaris, June 26 (Cockerell).

## Melissodes Martini, sp. n.

q. -Length about $13 \frac{1}{2} \mathrm{~mm}$.

Black, with a broad but convex abdomen, which has a dullish surface; pubescence of head and thoras pale, dull whitish below, more ochreous above, but nowhere brightcoloured ; posterior part of mesothorax, and scutellum except hind margin, bare, these bare areas fringed with black hair, most abundant on scutellum laterally ; bare area of mesothorax shining, with large well-separated punctures, that of scutcllum closely punctured; clypeus very densely punctured; hair of labrum pale reddish; mandibles reddish in middle, the subapical orange streak minute; vertex with a few black hairs, directed forwards and easily overlooked; eyes light sea-green ; facial quadrangle cousiderably broader than long; flagellum, except at base, dark red beneath; tegulæ dark, posterior part reddened. Wings strongly yellowish smoky throughout ; first recurrent nervure joining second submarginal cell (which is comparatively narrow) near the beginning of its last third. Hair of legs mainly pale, ferruginous on inner sides of tarsi, sooty on outer side of anterior tarsi and the apex of their tibize, and more or less sooty or brown on outer side of middle tarsi; tuft on hind knees fuscous; scopa of hind legs (in type full of creamy-white pollen) yellowish white. Hind margin of first abdominal segment narrowly white; base of first segment with erect white hair (no black intermixed); extreme base of second with white hair; median narrow snow-white hair-bands on segments 2 to 4 , that on 2 linear and interrupted in the middle, those on 3 and 4 slightly angled in the middle, or that on 4 may extend to the hind margin of the segment, thus becoming
very broad; basal part of fourth segment with a few long black bristles; the two apical segments and the venter, clothed with black hair. Easily known from M. gilensis by the black abdomen with narrow white bauds ; from M. petulca by hair on occiput not fulvous, the dark tegule, the short second submarginal cell, \&e.; from $M$. communis by the yellowish wings, the light scopa of hind legs, the larger size, \&c.

Hab. Gallinas River at Las Valles, New Mexico, Aug. 6, two specimens (T.D. A. \& W. P. Ckll.).

Named after my little son, who accompanied me on the expedition that led to its discovery.

## Melissodes thelypodii, sp. n.

ㅇ.-Length about 15 mm .
General appearance and markings of abdomen like M. Martini, but differing as follows:-Pubescence of thorax above bright fulvous, without any black, and covering more of mesothoras; black hairs of vertex more conspicuous, being long and erect; eyes not so green, the lower part perhaps reddish in life ; face more hairy, the hair faintly yellowish; clypeus more closely punctured; flagellum brighter red bencath; tegula apricot-colour. Wings larger, more dusky, and less yellow; first recurrent nervure joining second submarginal cell near its end ; outer side of third submarginal cell rounded (angled in Martini); hair on first abdominal segment pale fulvous, that at base of second more or less of the same colour. In both species, the small joints of the middle and hind tarsi are red.

Hab. La Cueva, Organ Mts., New Mexico, about 53:300 ft., at flowers of Thelypodium linearifolium, Sept. 4 (C.H.T. Townsend).

A pretty species, from the contrast between the black of the abdomen, with whitish bands, and the red of the thorax and hind tarsi.

## Melissodes Hewetti, sp. n.

q.-Length about or nearly 15 mm .

Of robust build, with a broad abdomen ; vertes and thorax above with bright fulvous hair; posterior part of mesothorax and scutellum except hind margin bare, these bare areas not surrom at sides of scutellum; bare area of mesothorax shining, with strong rather close punctures (closer and rather smaller than
in Martini) ; sides of vertex with erect dark hairs, not very numerous; face and cheeks with rather dull white hair; facial quadrangle broader than long, but not very greatly so; eyes very pale greenish; flagellum, except at base, dark red beneath; tegulæ dark red-brown. Wings very little dusky, much clearer than in M. thelypodii; first recurrent nervure joining second submarginal cell about the beginning of its last third; second submarginal cell nearly as broad above as high. Hair of legs pale; dark grey on outer side of antcrior tibie; tuft on hind knees rufo-fulvous; scopa of hind legs fulvous, hair on inner side of their tarsi bright ferruginous; small joints of tarsi ferruginous. Abdomen broad (broader than in thelypodii), with the hair on the first four segments ochreous tinged with fulvous, the arrangement of the hair as in thelypodii; hair of two apical segments very dark purplish brown; hair of venter fulvous (in thelypodii less abundant, and black, with some dull white laterally). By the colour and appearance of the abdominal bands this resembles $M$. gilensis, but it is larger, and the pubescence of the thorax is quite different, much more resembling that of M. menuacha. In many respects, M. Hewetti resembles M. texana, but it differs in having the hair on the face white and the abdominal bands fulvo-ochraceous.

Hab. Santa Fé, New Mexico, Aug. 2, 1894, at flowers of Cleome servulata; collected by myself. It was accompanied on the flowers by Nomia Foxii, D. T.

Named after Mr. L. L. Hewett, in recoguition of his educational and scientific work in New Mexico.

## Melissodes parosetre, sp. n.

## ठ. -Length about 9 mm .

Antennæ very long (about $8 \frac{1}{2} \mathrm{~mm}$.), flagellum bright fulvoferruginous beneath; clypeus, labrum, and a large patch on mandibles lemon-yellow; second joint of maxillary palpi swollen, third long and cylindrical, last minute; facial quadrangle longer than broad, narrowing below; hair of face and cheeks white, of vertex and occiput ochraccous; eyes silver-grey with a green tint: hair of mesothorax fulvous; scutellum with much black hair ; tegulx dark brown, hairy. Wings almost clear, stigma and nervures dark ferruginous; scoond submarginal cell large, receiving first recurrent nervure about the begimning of its last fourth. Hair of legs white, orange-fulvous on imer side of tarsi, which are red ; abdominal bands creamy white; hair of venter pale. Looks much like a small $\delta$ of M. grindelice, but easily separated
by the much longer antemme, red tarsi, \&e. From M. ayilis it is known by the black hair on scutellum, red tarsi, dec. ; from M. floris by the longer antemae, wings not yellowish, \&e.; from M. montana by the much smaller size, abdomen less covered with hair, \&c.

Hab. Mesilla, New Mexico, at flowers of Parosela scoparia, July 25 (Cockerell).

University of Colorado, Boulder, Colorado, U.S.A., March 16, 1905.
LXIX.-The Systematic Arrangement of the Fishes of the Genus Arges. By C. Tate Regan, B.A.
In my monograph * of the Loricariide I included nineteen species in the genus Arges. Messrs. Evermann and Kendall $\dagger$, who have received some fishes of this genus from Eenador, have written a short paper in which they consider the characters which I have used for the distinction and arrangement of the species as of very little value.

With regard to the structure of the adipose fin, Messrs. Evermann and Kendall, describing the specimens they have received, write: " When first received these examples revealed no trace of an adipose fin excepting what was soon discovered to be a short spine, sometimes naked but in most cases concealed under the skin, evidenced only by a slight elevation, which was at first regarded as a 'short adipose fin' ; but in alcohol there gradually appeared on the back a low, thick, fleshy fold which increased in resemblance to a thick adipose fin with their continuance in the preservative, and, in the smaller individuals, became thin and very much like an adipose fin in appearance." They proceed to quote Steindachner's descriptions of the adipose fin in Arges sabalo, A. longifilis, A. prenadilla, and A.perwames, and they then state: "These descriptions show conclusively that what has been so regarded is not a true adipose fin, which conclusion our specimens substantiate. It is evident that the presence of the supposed adipose fin on the different species is simply due to the action of the preservative and that there is no true adipose; and the smaller the individual and the longer

[^59]its stay in the preservative, the more like an adipose fin the fold may become."

Sufficient has been said to show that Messrs. Evermann and Kendall regard the structure of the adipose fin as of little value for the distinction of species. They state that their specimens undoubtedly belong to one species and yet that iudividuals fall respectively into several of my main divisions (based on the structure of the adipose fin), the only condition unrepresented being that of a well-developed adipose fin without trace of a spine, which they would hardly expect to find in specimens which have been only so recently submitted to the action of alcohol.

The position of the ventral fins is a character to which I have attached considerable importance for the distinction of species, but the authors quoted above state that in the males the ventrals are inserted farther forward than in the females, and they give figures of a male fish in which the insertion of the ventrals is below the origin of the dorsal, and of a female with the ventrals inserted below the middle of the dorsal. They continue: "In the males, as already remarked, the rentrals are inserted farther forward than in the females; therefore, comparison of extent of pectorals with ventrals or ventrals with proximity to vent is of no value. In fact, there is such a range of variation in these characters, regarded by Regan as showing specific differences, that there arises a serious distrust of the value of any of them for that purpose."

They conclude that the number of species should be considerably reduced, suggesting that the five alleged Peruvian species may be one, or at the most two. They cousider A. prenadilla and $A$. Eigenmanni to be synonyms of A. cyclopum, suggest that $A$. homodon may be the mate of A. Guentheri, and think that the characters given for the distinction of A. Whymperi, A. fissidens, A. sabalo, A. Taczanowskii, and $A$. Vaillanti are scarcely sufficient.

On receiving Messrs. Evermann and Kendall's surprising paper I at once proceeded to re-cxamine all the specimens of Aryes * in the British Museum Collection, with the result that I must entirely adhere to my original arrangement, Messrs. Evermann and Kendall's views being evidently the result of a hasty study of insufficient material.

I maintain my grouping of the species according to the structure of the adipose fin. The first division, to which the Pimelodus cyclopum of Humboldt most certainly

* 85 specimens, representing 16 or 17 species, from Peru, Ecuador, Colombia, and Venezuela.
belongs, is characterized by the presence of a well-developed, freely movable spine, as represented in my figures of Arges homodon and A. Guentheri, and in Boulenger's of $A$. Boulengeri. In the three specimens of $A$. Boulengeri and the eight of $A$. Guentheri which I have examined this feature is constant. The next group, comprising A. Eigenmanni, A. Il hymperi, and A. Vaillanti, is characterized by a weak or moderate, sometimes scarcely distinet, rather elongate adipose fin, with a small but distinct spine constantly present \%, more or less projecting in very young specimens and completely imbedded in the adult. This description applies to the single specimen of A. Whymperi, the three of $A$. Vaillanti, and the nineteen of $A$. Eigenmanni, varying in length from 33 to 100 mm ., which I have examined. From these $A$. orientalis and $A$. brachycephalus differ in the absence of the spine, although what appears to be a nodule-like rudiment may rarely be present in the former. I have examined ten specimens of each of the two last-mentioned species.

I am quite unable to see any discrepancy between Steindachner's descriptions of $A$. sabalo and $A$. longifilis and his figures of those species, which are both described and represented as having an elongate and well-developed adipose fin. Such an adipose fin is also characteristic of other species allied to these and represented in the British Museum Collection.

With regard to the structure of the adipose fin, then, it may be said that, making due allowance for slight differences due to size, individual variation, and state of preservation, there is a remarkable uniformity in members of the same species, whilst between the various members of the genus considerable differences exist, which form a convenient basis for the arrangement of the species.

I have been able to examine and compare male and female examples in each of the following species:- $A$. Guentheri, Boulengeri, Eigenmanni, orientalis, brachycephalus, festa, and peruanus. In none of them can I find the slightest difference between the sexes in the position of the ventral fins, which vary only slightly as to their point of insertion in individuals of the same species, but without regard to sex. Consequently I still attach considerable importance to the position of the ventral fins for the distinction of the species of this genus, whilst the other characters which I have

[^60]regarded as specific still appear to me to have the same value as before.

With regard to the suggested reduction in the number of species: I have never seen an Arges with the ventral fins inserted under the middle of the dorsal, as in the fish figured by Evermann and Kendall * and as in Steindachner's figure of Aryes prenadilla. In nearly all the specimens I have seen of $A$. Eigemmann the insertion of the ventral fins may fairly be described as exactly opposite to the origin of the dorsal, in a few it is slightly in advance of the origin

Arges Eigenmanni: male, female, and immature examples.
of the dorsal, and in one specimen (a male) it falls in the vertical from between the bases of the first and second dorsal rays. Consequently I am quite unable, at any rate until I have secn examples corresponding to Arges prenadilla, to accept the view of the specific identity of $A$. Eigenmami and $A$. prenadilla.

A comparison of the figures given here of A. Eigenmanni

[^61]with those published of A. homodon, Guentheri, and Boulenyeri and with that of Humboldt's Pimelodus cyclopum, will show with sufficient clearness that the first-named species differs very considerably from the others in the structure of the adipose fin and that there cannot be the least doubt that A. Eigenmanni is not identical with Humboldt's fish. A. homodon is most certainly not a male example of A. Guentheri, from males of which species it diffirs not ouly in the much more anterior insertion of the ventrals, but also in the much more posterior position of the rent, the more posterior situation of the spine of the adipose fin, and in other characters also.

The suggestion that the Peruvian species, viz, A. lomgifilis, sabalo, Taczanouskii, peruamus, and Simonsii, in reality represent only one or two, cannot be entertained. A. peruanus and $A$. Simonsii present so peculiar a dentition that I was in doubt as to whether they ought not to constitute a distinct genus, and as the latter species is represented by larger specimens (a in number) in which the barbel is nearly twice as long as in the smaller examples of $A$. peruanus, there can be no question as to the validity of these two species. The other three differ from each other so widely that there can be no excuse for confounding them, and I need only refer to my synopsis of the specics and to the published descriptions and figures.

In the whole genus the only point as to which I entertain some doubt is as to whether $A$. Eigenmami is distinct from A. Whymperi. The latter is based on a single specimen and it is probable that the somewhat shorter ventral and more posterior vent may be due only to individual variation. A. Vaillanti, based on three sperimens (not one only as stated by Messrs. Evermann and Kendall) with a much shorter caudal peduncle ( $6-6 \frac{1}{2}$ in the length of the fish, instcad of $4 \frac{2}{3}-5$ as in A. Eigenmanni), is certainly distinct.

Some other points in Messrs. Everman and Kendall's paper call for comment. They consider that the clongate anal papilla of the male fish represents the first anal ray of the female. This view is completely negatived by the structure of the papila, by the fact that it is constantly present in the female, although smaller, and by the obvious homology between the first subspinous ray of the anal fin in the two sexes. Moreover, difference in the number of anal rays is either individual or specific, not sexual.

The American authors prefer the generic name Cyclopium to Arges, whatever the objections which may be urged against it on the ground of its formation. This, of course, is
a matter of opinion, but they afterwards state: "But whatever view may be held on this ground, Mr. Regan's contention does not hold in the case under consideration. Cyclopium is not the genitive plural of Cyclops, as he imagines, but the neuter form of the adjective cyclopius." I do not know what reasons Messrs. Evermann and Kendall may have for this assertion, but Swainson's \% own words, as quoted by me (and not as misquoted by them), seem to establish beyond any doubt that he merely took the specific name, without alteration, and used it for his new genus.

The statement that I object to the family name Argiidæ of Gill is hardly correct. On the contrary, I should consider it a most excellent name for the group if it is to be regarded as a distinct family. Provided that they be correctly defined and their relations made clear, it appears to me to be a point of comparatively small importance whether the Argiinæ or Argiidæ be regarded as a specialized group of Loricaridee or as a distinct family. I am inclined to believe, however, that the practice of making every somewhat abnormal or peculiar genus the type of a family tends to obscure its relationships.
LXX.-On some Oriental Aphodiid Coleoptera of the Rhyparus Group, with Description of a new Genus. By Gilbert J. Arrow.
The British Museum having recently received from Mr. George Lewis a very remarkable minute beetle having no close ally among known genera, I have founded for it a new genus which can only be associated with Rhyparus. In the course of studying its affinities I have made a few notes upon certain other species of this peculiar group which I publish at the same time.

## Stereomera, gen. nov.

Corpus bresiter rectangulum, depressum; caput magnum, clypeo late arcuato ; antenme 9 -articulate, articulo primo longo, lunato, in fossa profunde volvente, sccundo breviter cylindrico, tertio fere ad tria sequentes conjuncta ærquale, his inter se aqualibus, tribus ultimis clavam brevem formantibus; palpi maxillares longi, graciles; oculi elongati; coxæ anteriores quatuor laminibus

* Swainson, of course, misquoted IIumboldt, substituting Pimelolus cyclopium for Pimelodus cyclomum.
angustis separatæ, posticæ contigux, prosterno antice et postice valde producto; pedes omnes breves, tibiis sine dentibus vel carinis, tarsis omnibus 3 -articulatis, articulis brevibus, crassis ; elytrorum epipleure latæ; abdomen valde contractum, segmenta in medio solidati; pygidium ventrale.

## Stereomera pusilla, sp. n.

Lata, valde depressa, rufo-picea; capite lato, plano, prothoracis atque elytrorum lateribus exacte coadaptatis, fere rectis et parallelis; prothorace antice lesiter angustato, angulis omnibus acutis, parte mediana antice et postice valde elevata ibique breviter longitudinaliter costata, margine postico valde sinuato; elytris brevibus, epipleuris latis, lateribus parteque postica abrupte verticalibus, singulo elytro costis tribus internis pluribusque transversis ornato.
Long. 2.5 mm .

## Hab. Singapore.

A single specimen of this minute beetle, found by M. Raffray in November 1889, has been kindly given to the National Collection by Mr. George Lewis. Although having no superficial resemblance to any other genus of Aphodiidæ, such of its structural features as are not entirely peculiar point clearly, in my opinion, to a place in that family. The 3 -jointed tarsi, much-reduced abdomen, and the form of the thorax and elytra isolate it from all known genera, but in its general anatomy it shows many points of relationship with Rhyparus.

The head is large and unarmed, the thorax short and broad, with a deep transverse furrow about the middle which interrupts a series of longitudinal costr continuous with similar costre upon the elytra. These are also obliterated in front of the scutellum by a sharply elevated boss. The elytra exactly fit against the prothorax behind, and at two thirds of their length become rather abruptly perpendicular. The sides are also abruptly perpendicular, and broad folds wrap the abdomen beneath, the elytra being immovable and the suture entirely obliterated. There are three longitudinal costax on each side in addition to the lateral carina, and the last interval is about twice the width of the others. The intervals are crossed by fine transverse ridges, which produce a reticulated appearance. The angles formed by the lateral carinæ at the declivity are somewhat turned inwards.

The head in the contracted position fits against the front femora, entirely enclosing the eyes and antemme, the latter fitting into deep fosse in the lower face of the clypeus. There is a very long and slender anterior prosternal process
and a rather long tapering postcoxal process. The middle coxæ are separated by a thin lamina and the hind cosæ are contiguous. Between middle and hind coxæ the metasternum is raised, forming a trapezoidal area. The pygidium is completely ventral, and between it and the metasternum only two ventral segments are distinguishable in the middle, but five or six immovably united can be counted at the sides. The ventral surface is coarsely punctured.

The most remarkable feature of all is found in the tarsi of three joints only, any less number than the coleopterons maximum of five being of extreme rarity among the Lamellicornia. Another abnormal genus of Aphodiidæ (Phycochus) has, however, tarsi of only two visible joints. The articulations in Stereomera are very close, and can allow very little, if any, movement. Similarly modified tarsi are found in a few Cetoniidæ (Trichoplus and Callinomes) living in ants' nests. Stereomera has in all probability the same habit, for the domestic animals of ants, like those of man, are great violators of the proprieties of systematics.

Although the species of this little group first described was placed by Westwood among the Aphodiidæ, subsequent writers-Harold and Fairmaire-have treated them as Copride. There is no justification for this view except Pascoe's inaccurate description of one of the species, called by him Antrisis Saundersi, although congeneric with lihyparus, Westwood, and, I believe, identical with the laterdescribed R. approximans, Fairmaire. Pascoe described the hind coxa as widely separated, being evidently deceived by the separation of the femora, which are inserted at a distance from the tips of the coxæ, the latter being really contiguous. Mistaking the inturned pygidium for a ventral segment, he called the abdomen six-jointed, whereas there are only five joints. His figure is also misleading, representing the insect as much too short. In my opinion these forms constitute a link between the Aphodiidæ and Trogidæ. The abdomen of five visible segments, the simple legs without teeth or spines, and the conformation and sculpture of the surface connect them with the Trogidæ, the dilatation of the clypeus, the prominence of the abdomen, the position of the pygidium, \&c., exclude them from that family, and the closely approximated coxa and 9 -jointed antenne are features common to both those families but foreign to the Copridæ.

The list of Rhypari at present described amounts to a dozen, but it will no doubt become very much longer. A third of the number are from Borneo, but the distribution is very wide, extending from Sud-Est Island (Louisiade

Archipelago) in the east to Nauritius in the west, and I have even seen (in M. René Oberthür's collection) a species from West Africa. The only mainland species yet recorded is R. birmanicus, Fairm.; but R. sumatrensis, Fairm., was found by Doherty at Perak, and I describe here another form occurring in the same locality.

## Rhyparus peninsularis, sp.n.

Niger, opacus, griseo-indutus, modice elongatus; capite lato, (jcristato; prothorace antice valde dilatato, angulis rotundatis, lateribus medio sat dilatatis, deinde contractis, angulis posticis obtusis, disco (6-carinato, carinis duobus internis leviter sinuatis, medio paulo approximatis, duobus intermediis late interruptis, externis integris, intervallis medio et externis sparse grosse punctatis, intermediis leribus; elytris acute costatis, costis suturalibus paulo latioribus, postice regulariter arcuatis, discoidalibus postice abbreriatis, valde incrassatis, callis apicalibus prominentissimis, intervallis grosse biseriatim punctatis, lateribus haud parallelis, postice distincte contractis; pygidio longitudinaliter carinato; corpore subtus sat erebre punctato; tibiis quatuor anterioribus apice ralde incurratis, femoribus intermediis subtus bidentatis.
Long. 6-7 mm.
IIab. Malay Peninsula, Penang (Lamb), Perak (Dulevety).

I have seen three specimens, of which that from Perak is in M. Oberthür's collection.

The species resembles $R$. Saundersi, Pascoe, and still more another Bornean form which I have seen identified by M. Fairmaire as his $R$. approximatas, but which more nearly agrees with the description of $R$. denticollis, and may be distinct from both. $R$. peninsularis is rather larger than either and relatively broader, with its elytra tapering more behind. It differs most obviously in its puncturation, the inner lateral interstices of the pronotum being smooth and the middle and outer interstices thinly strewn with large punctures, whereas the other species named have the pronotum evenly and densely punctured. The punctures upon the elytral interstices are also very large and arranged in not closely serried rows. The elytra are not angulated behind at the suture, as in R. Saundersi. R. sumatrensis, Fairm., is also a nearly related form, but it is still larger and the pronotum is almost entirely impunctate.

## Rhyparus philippinensis, sp. n.

Niger, opacus, elongatus, parallelus; capite lato, 6 -cristato, cristis duabus frontalibus exiguis; prothorace modice transverso, 6costato, costis sat crassis, intervallis sat grosse punctatis, costis duabus mediis antice et postice leviter divergentibus, intermediis interruptis, laterum angulis anticis mediisque arcuatim productis ; clytrorum costis suturalibus latis, postice regulariter arcuatis, discoidalibus postice interruptis, incrassatis, callis apicalibus prominentibus, interstitiis omnibus sat grosse biseriatim punctatis; pygidio longitudinaliter carinato ; corpore subtus sat crebre punctato; femoribus simplicibus, tibiis quatuor anterioribus apice incurvatis.
Long. $5-6.5 \mathrm{~mm}$.

## Hab. Philippine Islands.

Four specimens of this species have been in the British Museum since 1845, and M. Oberthür possesses another example. They are almost destitute of the earthy covering usually found in these beetles, but this is probably only due to local or accidental circumstances. The species is similar to the preceding one except in matters of detail. It is rather smaller and more slender, and the prothorax is everywhere rather coarsely punctured, a few punctures being traceable even upon the costr, which are rather thick. The rows of punctures upon the elytra are rather less coarse than in $R$. peninsularis. The pygidium and underside are as in that species, but the middle femora are not toothed.

## Rhyparus gracilis, sp. n.

Niger, opacus, elongatus, parallelus; capite modice lato, punctato, medio tumido, minute bituberculato, postice 4 -cristato, clypeo obtuse biangulato, medio recto ; prothorace postice latitudine ad longitudinem æquali, lateribus antice et medio arcuatim dilatatis, carinis duabus medianis postice late divergentibus, intermediis vestigiis anticis et posticis ostensis, externis valde sinuatis, intervallis grosse punctatis; elytris ut in $R$. philippinense, sed paulo longioribus, callis apicalibus modice prominentibus; pygidio apice longitudinaliter carinato; corpore subtus crebre punctato; femoribus quatuor anterioribus subtus angulatis, tibiis omnibus apice fortiter incurratis.
Long. 6.5 mm .

## Mab. Louisiade Archipelago, Sud-Est Island.

Three specimens were collected by Mr. Meek in April 1898, one of which has been presented by M. Oberthür to the Museum.

The species closely resembles $R$. philippinensis, but is
larger and still more slenderly proportioned, the thorax, exclasive of the anterior projections, being nearly quadrate. The head is less transverse and less angular than in most of the species, and the frontal tubercles are widely separated from those on the vertex. The thorax is coarsely punctured all over, and its central carine are close together in front, begin to diverge before the middle, and are wide apart behind. The second carina on each side is very broadly interrupted. The front and middle femora are broadly but sharply angulated beneath.

The genus Sybacodes is closely related to Rhyparus, but its form is more normal and, except for the thoracic ridges, almost that of Atrenius. The only known species, S. lutulentus, Fairm., originally described from Burma, has a wide distribution, and I have seen it also from Siam, Kanara, and the Panjab. M. René Oberthür has kindly enabled me to compare our series with the types, and as M. Fairmaire's description is ambiguous and in some respects inaccurate, I have thought it desirable to give a redescription, based upon the fuller materials at my disposal.

> Sybacodes lutulentus, Fairm.
> ('Notes from the Leyden Museum,' 1896, pp. 84-85.)

Robustus, griseo-indumentus, subtiliter auropiliferus, clypeo obtuso biangulato, fronte fasciculis duabus aureis ornata; prothorace sat lato, angulis anticis fere rotundatis, posticis excisis, lateribus ante medium lævissime contractis, disco longitudinaliter 6 -costato, costis internis duabus fere rectis, externis valde sinuatis, intermediis medio intus fossa parva deflectis, haud interruptis, omnibus breviter auropiliferis; prothorace capiteque irregulariter haud dense punctatis; elytris ad humeros quam prothorace latioribus, deinde lateribus leviter sat regulariter arcuatis, sutura costisque tribus fortiter, intermediisque quatuor minus elevatis, auropiliferis, interstitiis uniseriatim sat grosse punctatis ; pygidio quam longitudinem multo latiore, crebre et grosse punctato, carina longitudinale pilifera; tibiis anticis bidentatis, spind apicale breve ac robusta, tarsis sat brevibus.

## Long. 7 mm .

Hab. Panjab, Kangra Valley; S.W. India, Kanara; Burma, Carin Cheba, Ruby Mines; Siam, Renong.

This genus has an obvious affinity with Rhypares, but seems to represent a less extreme degree of specialization. The general contour of the head and thorax are the same, but all the elevated portions of the surface are clothed with
fine silky yellow hair. The elytral costr are twice as numerous as in Rhyparus, a secondary series, less elevated, alternating with the primary series. M. Fairmaire's comparison of the elytral sculpture with that of Sybax impressicollis seems to be due to a misconception, for that genus is very different in every respect and has very broad and flat intervals between the costæ. There are no elytral pits or callosities in Sybacodes, the head is relatively smaller than in Rhyparus, the metasternum shorter, and the last abdominal segment longer. M. Fairmaire has described the front tibio as threetoothed, but he has evidently mistaken the strong terminal spine for the apical tooth.
LXXI.—Descriptions of Seven new Species of Notodontidæ from Tropical South America. By Herbert Druce, F.L.S. \&c.

## Hippia undulata, sp. n.

Male.-Head, antennæ, collar, tegulæ, and thorax yellowish brown; thorax and abdomen brown; anal tuft yellowish white ; legs yellowish brown. Primaries dark fawn-colour, crossed from the costal margin to the inner margin by a number of fine undulating blackish-brown lines, some of which are broken into small spots; beyond the cell a rather large brown spot: secondaries blackish brown, palest at the base and along the inner margin; the fringe fawn-colour.Female very similar to the male, but paler in colour and with all the markings more distinct.

Expanse, $\delta 1 \frac{1}{2}$, ㅇ $1 \frac{3}{2}$ inch.
Mab. Colombia, Minca, 2000 feet (HI. MI. Smith, Mus. Druce).

## Blera argentata, sp. n.

Male.-Head, antennæ, and palpi black; collar and thorax dark bromn; tegulæ silvery grey; abdomen pale greyish brown; the anal segments clothed with black hairs ; underside of thorax and abdomen yellowish brown; the legs dark brown. Primaries dark silvery brown; a line crossing the base of the wing and the discal spot yellowish brown; two narrow waved black lines cross the wing from the costal to the inner margin, the first about the middle, the second
beyond the cell; the outer margin broadly silvery grey; a marginal row of black streaks extends from the apex to the anal angle: secondaries pale greyish brown, slightly yellowish along the inner margin.

Expanse 13 $\frac{3}{4}$ inch.
Hab. S.E. Peru, Santo Domingo, 6000 feet (Mus. Druce).

## Meragisa Garlepi, sp. n.

Male.-Head, collar, tegulæ, and thorax pale olive-green ; antenne brown; abdomen above dark brown, the sides and underside yellow, the anal segment yellowish brown thickly irrorated with small brown scales; underside of thorax and legs yellow. Primaries pale olive-green, crossed from the costal to the inner margin by three narrow fawn-coloured bands, edged with black, the first near the base, the second before the middle of the cell, the third beyond the cell; the orbicular spot white ; a greyish-white waved submarginal line extends from the apex to the anal angle; a marginal row of black dots from the apex to the anal angle; the fringe alternately yellow and brown: secondaries blackish brown, the base, imner margin, and the fringe pale yellow. Underside of both wings pale yellow, shaded with dark brown, the outer margins yellow.

Expanse 23 $\frac{3}{4}$ inches.
Mab. Bolivia, Songo (Garlep, Mus. Druce).

## Meragisa semifulva, sp. n.

Male.-Head and thorax grey, thickly clothed with reddishbrown hairs; palpi black, the third joint small, clothed with yellow hais; collar and tegule reddish brown; antennæ brown ; abdomen blackish brown, the basal segment yellow, the anal segment greyish brown; underside of the thorax and abdomen yellow; legs yellow. Primaries greyish white, crossed from the costal margin to the inner margin by a series of lunule-shaped reddish-brown lines; orbicular spot yellow ; the base and centre of the wing shaded with yellow; a marginal row of black spots extends from the apex to the anal angle; the fringe alternately reddish brown and yellow: secondaries brownish black, the inner margin broadly banded with pale yellow, the fringe yellow. Underside pale yellowish white, clouded with blackish brown.

Expanse $2 \frac{1}{4}$ inches.
Hab. S.E. Peru, Santo Domingo, 6000 feet (1Fus. Druce).

## Lobeza Sinithi, sp. n.

Female.-Head, palpi, collar, tegulæ, and thorax grey ; abdomen yellowish white, the sides thickly clothed with white hairs ; antenne reddish brown; underside of the thorax, abdomen, and legs white. Primaries greyish white, thickly irrorated with reddish scales; a reddish-brown band crosses the wing near the base: sccondaries greyish white; the fringes of both wings grey. Underside of both wings sordid white.

Expanse $2 \frac{1}{4}$ inches.
Mlab. Colombia, Don Amo, 2000 feet (II. II. Smith, Mus. Druce).

## Hemiceras affinis, sp. n .

Male.-Ilead, collar, and tegulæ reddish fawn-colour, back of the head white ; antennæ dark brown ; thorax and abdomen dark brown; underside of thorax black; legs and underside of the abdomen greyish fawn-colour. Primaries fawn-colour, crossed beyond the middle from the apex to the middle of the inner margin by a dark brewn line, palest on the outer edge ; a stiaight brown line crosses the wing near the base, but does not reach either margin; the fringe dark brown: secondaries white, the outer margin shaded with fawn-colour, and no opaque spot near the anal angle; fringe white. Underside of both wings cream-colour, the primaries shaded with fawncolour along the costal margin and at the apex.-The female very similar to the male, but larger.

Expanse, ơ 2, ㅇ $2 \frac{1}{4}$ inches.
Hab. N. l'eru, Huancabamba, 6000-10,000 feet; S.E. Peru, Santo Domingo, 6000 feet (Mus. Druce).

## Hemiceras Buckleyi, sp. n.

Male-Head, collar, tegula, and thorax brown, thickly irrorated with greyish scales ; antemm and palpi dark brown; abdomen above greyish brown, underside almost white. Primaries dark fawn-colour, inrorated with brown scales; the orbicular spot dark brown; a submarginal dark brown line extends from the apex to the inner margin: secondaries pale reddish brown. Underside of both winge brownish white.

Expanse $2 \frac{1}{4}$ inches.
Hab. Ecuador, Sarayacu (C. Buckley, Mus. Druce).
LXXII.-Descriptions of a new Genus and Four Species of Coleoptera from New Zealand. By Capt. 'I'. Broun, F.E.S.

## Group Cnemacanthidæ.

## Metaglymma Doullii, sp. n.

Elongate, nitid, black; antennæ, legs, and labrum piccorufous.

Head narrowed anteriorly, not constricted behind the small but very prominent eyes, with irregular ruge near these; epistome truncate, with three or four wrinkles; labrum medially incurved, with five punctures. Antenne of moderate length, the last six joints sparingly pubescent. Thorax rather narrow, 2 lines long by 212 broad, its sides very gently rounded and a good deal, but not abruptly, narrowed behind, posterior angles obtuse; its surface smooth, with the usual groove along the middle, basal fovere small, not transverse, and placed close to the angles; lateral rims not explanate. Elytra oblong-oval, their strire deep, even near the suture; the punctures are coarse and the transverse intervals between them rarely attain the level of the longitudinal interstices; the inmer three interstices are moderately wide, the others become narrower; the apical sculpture is also deep, but more irregular. Pygidium smooth.

Tibice stout; the outer angle of the anterior does not reach the apex of the basal tarsal joint, that of the intermediate is moderately, the posterior but little expanded.

Unclerside almost quite smooth and shining, with three punctures at each side, at the extremity, of the last ventral segment.

In 11 . monilifer the lateral margins of the thorax are flattened, with well-marked transverse fovea-like sculpture.

Although I have not seen Dr. Sharp's M. sulcatum (no. 1764), I consider the present species its nearest ally ; it is, however, distinct therefrom, as in the former the head is without sculpture and the hind body is parallel-sided.
$\delta^{\pi}$. Length $8 \frac{1}{2}$, breadth 3 lines.
North Canterbury.
One example from the Rev. Alexander Doull, in whoze honour it has been named.

## Metaglymma minor, sp. n.

Piceous black, rather dull; legs and antennæ pitchy red. Hcad smooth; labrum rounded and punctate in front;
eyes prominent. Antenne all but nude and shining, bearing only a few slender outstanding hairs. Thorax much contracted near the base, $2 \frac{1}{\mathrm{~g}}$ lines broad by 13 long, very slightly rounded laterally ; apex truncate, a little emarginate medially at the base, the sides (margins) expanded and somewhat flattened, but narrow at the basal angles, which are obtuse ; its surface is smooth, having only the common median sulcus and moderately long fossæ. Elytra oblong-oval, narrower at the shoulders than on top of the hind slope; moderately punctate-striate ; the discoidal strix and punctures are rather shallow, those near the sides are coarser, but not deep; the interstices are simple.

Legs stout, the outer apical prolongation of the anterior tibia does not extend beyond the middle of the first tarsal joint, the intermediate tibix are moderately and the hind pair slightly thickened at the extremity.

Underside nearly smooth and as red as the femora. Terminal ventral segment with two punctures on each side of the midile at the apes, the intermediate with four punctures at the middle.

This species looks like a small M. monilifer, which, however, has a series of about twelve punctures across the extremity of the penultimate ventral segment, with stouter legs and more strongly developed tibial angles, larger but less convex eyes, and slight differences of sculpture.
$0^{7}$. Length 7, breadth $2 \frac{1}{2}$ lines.
North Canterbury.
One from the Rev. A. Doull's collection.

Group Heleidæ.

## Cilibe costella, sp. n.

Opaque, fuscous black; antennæ, palpi, and tarsi pitchy red; oblong, only slightly oviform, moderately convex.

Head densely, moderately coarsely, and irregularly punctured, most coarsely on the lateral spaces before the eyes; vertex convex; epistome emarginate, but less so than in C. opaculu. Thorax $3 \frac{1}{2}$ lines broad by $2 \frac{1}{4}$ long, including the front angles, distinctly marginate at the sides, these only slightly curved, almost straight behind the middle, narrowed anteriorly, with a feeble simuosity near each front angle; this latter is prominent and its tip appears incurved, the base is bisinuate, with rectangular angles; disk moderately convex, the sides somewhat flattened but not obviously concave, the whole surface coarsely and reticulately punc-
tured, interstices rather narrow. Scutellum curvilinearly triangular, punctate. Elytra rather wider than the thorax at the base and becoming gradually wider towards the hind thighs, from thence much narrowed apically; the sides, as far as these thighs, are evidently concave, but behind that point they are quite flat or depressed, with transverse fovere and punctures; the suture is plane, but on each elytron there are three more or less distinct discoidal coste, the two outer become convergent behind, there are also indications of other longitudinal interrupted lines between the coste ; the surface is irregularly and coarsely punctured, with narrow and apparently raised intervals as far as the second costre, but outside that area the sculpture is intermingled with numerous small grauular elevations, some of which almost form regular series towards the hind slope, so that the general sculpture in certain lights seems somewhat linear; the lateral margins are reflexed and minutely sculptured.

Legs and tarsi normal, closely and rugosely punctured, with fine flavescent pubescence. Antennce punctate, second joint rather longer than broad, third not twice the length of the following one; joints 4 to 8 longer than broad, 9 to 11 more rufescent and more finely pubescent, 11 oval.

Underside a little nitid, distinctly punctate, with a very minute seta in each puncture ; prosternum more coarsely and rugosely punctured.

The stature is that of $C$. opacula, but the sculpture bears more resemblance to that of the smaller C. gramulosa and C. rugosa, thus rendering this species unusually distinct.

Length $8 \frac{1}{2}$, breadth $4 \frac{1}{2}$ lines.
I am indebted to the Rev. Alexander Doull for the specimen found by him in North Canterbury.

## Group Rhyparosomidæ.

## Mrcanus, gen. nov.

Rostrum rather shorter than thorax, stout, broadest and pterygiate at the point of antemal insertion, so that it appears contracted behind; its apical portion smooth and shining, the remainder rugose-punctate. Scrobes quite open above in front, directed towards but not quite reaching the cyes. Mandibles prominent, laminate. Eyes almost rotundate, flat, distinctly facetted, just free from thorax and widely distant from each other. Antenne implanted before the middle. Scape stout, clavate, attaining the back part of the eye. Funiculus obviously longer than scape, basal joint only
one third the length of the scape, second distinctly shorter, joints $3-7$ slightly decrease in length, $4-7$ moniliform and hardly at all longer than broad. Club oval, triarticulate. Thorax subcylindric. Scutellum obsolete. Elytra oblongoval, wider than thorax at the base.

Leg.s of moderate length. Femora clavate. Tibice simple, their inner angles not prolonged and acuminate. Tarsi rather short, with finely pilose soles, their third joint bilobel; the lobes, however, are quite short.

Prosternum moderately incurved. Ocular lobes obsolete. Anterior coxce prominent and contiguous, intermediate moderately separated, the posterior widely. Abdomen elongate, the basal segment at the sides but little longer than the second, the suture medially incurved; the third and fourth about a third shorter than second (these and the second with straight sutures), filth rather long.

With some slight modifications the only exponent of this genus might be transformed into a Clypeorhynchus. This latter, however, has more slender and much longer antenne; the eyes, instead of being rotundate, are transverse, their greatest length being from above downwards; their third tarsal joint is formed of very elongate and distinctly separated lobes; the prosternum is more deeply and abruptly emarginate; the elytra are closely adapted to the thorax and at the base do not exceed it in width; the rostrum is nearly cylindrical throughout, whereas in Hycanus the anterior two thirds is of oviform outline, and the smooth apical portion is not limited by any definite suture.

## Hycanus Cockaynei, sp. n.

Subovate, slightly convex, opaque; fuscous, apex of thoras, elytral suture, and legs castaneous, tarsi testaceous, antema rufescent; very sparingly clothed with rather tine short grey setre, on the hind body, however, many longer erect ones occur.

Rostrum rather coarsely punctate, but smooth, shining, and reddish near the extremity; this part bears a few slender white hairs, but is not apparently marked off from the asperate portion by any basal suture; on the head there is a feeble longitudinal intervcular furrow. Thorax slightly longer than broad, widest near the front, slightly constricted at apex, gradually narrowed backwards; it is not uneven, there being only a short groove in front; its whole surface is densely and minutely sculptured, and the visible panctures
are only moderately coarse. Elytra oblong-oval, much narrowed posteriorly; they are punctate-striate on the disk ; towards the base and sides the punctures are distinct, but the striæ are not; the interstices are plane and minutely and closely sculptured. Anternce sparsely pubescent.

Underside with a few small grey seta; the prosternum with some coarse shallow punctures, the ventral segments finely sculptured.

Length (rostr. incl.) $2 \frac{3}{4}$, breadth $\frac{7}{8}$ line.
Auckland Islands.
Described from one example found amongst moss in July 1903 by Mr. L. Cockayne, in whose honour it has been named. The specimen was forwarded to me by Professor Chilton.

Auckland, 17th March, 1905.
LXXIII.-Natural History Notes from the R.I.M.S. Ship 'Investigator,' Capt. T. H. Heming, R.N., commanding.Series III., No. 7. Preliminary Report on the Deep-Sea Alcyonaria collected in the Indian Ocean. By Prof. J. Arthur Thomson, M.A., and W. D. Henderson, M.A., Carnegie Scholar, University of Aberdeen.

A rich and interesting collection of Decp-Sea Alcyonarians dredged in the Indian Ocean by the 'Investigator' was entrusted to us for examination and report by Prof. A. Alcock, LL.D., F.R.S., of the Indian Museum, Calcutta. As a second consignment received this year has more than doubled the original collection, it has scemed advisable to publish a brief preliminary notice of those forms which we have been able to examinc. We have not in this communication given anything like full diagnoses of the new forms or more than a few measurements; we have merely indicated the general nature of the first consignment of the collection. We hope to complete the report in the course of this year.

## Provisional List of Species.

Sympodium indicum, sp. n.

- incrustans, sp. n.

Clarularia decipiens, sp.n.

Sarcophytum parrum, sp. n.

- fungiforme, sp $n$.

Spongodes rosea, kilikenhal.

## Order STOLONIFERA.

## Family Cornulariidæ.

## Sympodium indicum, sp. n.

A specimen forming a complete tube round a hollow vegetable axis; the granular greyish-white cœnenchyma is thickly covered with large polyps irregularly arranged; the spicules are rough warted spindles and quadriradiate forms.

Locality. Andamans, 265 fath.
Sympodium incrustans, sp. n.
A large specimen encircling a fragment of the stem of a plant ; the whole surface of the membranous stolon and of the large polyps is covered with warty spindles and rods, many of which are visible to the naked eye; the polyps are mostly in groups of two or three.

Locality. Andamans, 371 fath.

## Clavularia decipiens, sp. n.

Two specimens of a remarkable and difficult form seem referable to the genus Clarularia. They envelop and almost conceal a straight siliccous axis $(0 \cdot 1-0 \cdot 3 \mathrm{~mm}$. in diameter, 70 and 110 mm . in length, probably the flinty fibre of a glass-rope sponge). The conenchyma is thin and consists mainly of a feltwork of spicules. The polyps, including the retracted tentacles, have a length of 3 mm ., and are
separated by intervals of $1-7 \mathrm{~mm}$. The calyx is ridged and abundantly spiculated. The spicules are warty spindles, the largest of which are $0.2-0.3 \mathrm{~mm}$. in length, while many are very much smaller.

Locality. Andamans, 238-.290 fath.

## Order ALCYONACEA.

## Family Alcyoniidæ.

Sarcophytum parvum, sp. n.
A small red colony attached to a piece of coral ; the capitulum is slightly mushroom-shaped; the polyps are more numerons and smaller round the margin, vary from 4-18 mm. in length, and are thickly coated with spicules; the polyp-spicules are (1) long rod and spindles with very fer and very small spines, (2) small clubs spinose at the broad end and interlocking to form a sort of feltwork, and (3) small double clubs.

Locality. Station 232, 430 fath.

## Sarcophytum funyiforme, sp. n.

A mushroom-shaped colony, red-brown in colour except the retractile portions of the polyps, which are yellowish; the autozooids are uniformly distributed over the surface and the numerous siphonozooids fill up the gaps; the spicules are (1) slender spinules with few spines, (2) smaller clubs spinose at the thick end, (3) still smaller double clubs, and (4) very minute irregular forms,

Locality. Station 204, 180-217 fath.

## Family Nephthyidæ.

## Spongodes rosea, Kükenthal.

A specimen which approximates closely to this species, except that some of the spicules are trice as long as the longest described by Kükenthal, and that the coloration is slightly different.

Locality. Bay of Bengal, 88 faths.

## Spongodes rakayre, Hickson \& Hiles.

A specimen which agrees almost thoroughly with this species except in a small detail concerning the projecting polyp-spicules.

Locality. Station 237, 90 fath.

## Chironephithya varialilis, Hickson.

Numerous fragments, probably belonging to one large colony, seem referable to this variable species; the deep coral-red spicules of the anthocodise form a striking colourcontrast with the white or pale pink branches.

Locality. Bay of Bengal, 88 fath.

## Order AXIFERA.

## Family Dasygorgidæ.

Dasygorgia ramosa, sp. n.
A profusely branched colony, the fifth branch directly above the first; a long slender polyp on each node; the polyp-spicules are arranged longitudinally, except for two small portions on each side of the base, where they are obliquely transverse; the spicules are warty spindles or flat sword-like forms with serrated edges. This form approaches D. spiculosa, but has smaller polyps and larger spicules.

Locality. Station 202, 695 fath.

## Dasygorgia aurea, sp. n.

Fragments of a colony with a beautiful golden-yellow asis, with helicoid branching-the fourth branch usually over the first; the polyps are bell-shaped, with eight projecting points, with spirally disposed spicules; the spicules are rods, spindles, and flat irregular forms mostly quite smooth. This form comes near D. squarrosa, but cannot be identified with it.

Loculity. Station 202, 695 fath.

## Strophogorgia Verrilli, W right \& Studer.

Three fragments seem referable to this species. In one the basal attachment is present and consists of a number of root-like processes very calcareous and translucent. The axis is hair-like, very calcareous, and brittle except at the tip; the spicules are irregular in shape, some of the spindles reach a length of 2 mm .

Locality. Andaman Sea, 375-490 fath.

## Herophila gracilis, sp. n.

A delicate graceful colony with branches coming off on all sides; the basal attachment consists of very calcareous semitransparent milk-white root-like processes; the axis is
yellowish and tapers to a thread-like fineness; the branches are disposed in a spiral and the axis is somewhat zigzag; the polyps are distant, usually only one on a node, in some parts all on one side, in other parts in an apparent spiral arrangement ; the polyp-spicules lie parallel to the long axis of the polyp exeept at the base, where they take an oblique direction and finally run parallel to the stem; the superficial spicules are short rods, rounded at the ends, and bearing very minute rough points; besides these there are quadriradiate spicules with an X-shaped marking, and a number of minute spherical spicules with relatively long projecting spines.

Locality. Station 241, 606 fath.

## Family Isidæ.

Ceratoisis palme, Wright \& Studer.
Two fragments which agree in every respect with the description given by Wright and Studer.

Locality. Andaman Sea, 500 fath.
Acanella rigida, Wright \& Studer.
A complete bushy colony, with branches in verticels of of two, three, or four, with prominent rigid polyps covered with fusiform spicules.

Locality. Laccadive Sca, 703 fath.

> Primnoisis alba, sp. n.

The basal portion is a broad calcareous plate; the axis with its alternate horny and calcareous joints is longitudinally grooved; the branches are given off from the calcareous internodes and begin with a horny node; the cœuenchyma is thin and creamy white ; the low roughly conical verruce occur in fours either in a spiral or in a whorl; the spicules are irregular flat disks and rods with numerous prominent warts.

Locality. Audamans, 270-45 fath.

## Family Primnoidæ.

## Primnoa Ellisii, von Koch.

This beautiful species, described by von Koch from near Naples, also found by Herdman off Ceylon, was obtained by the 'Investigator' at the Andaman Islands (2r0-1.5 fath.)a wide and interesting geographical distribution.

## Calypterinus Allmani, Wright \& Studer.

The branches arise alternately on three sides of the main stem; the iridescent axis shines through the thin conenchyma; the polyps occur in verticels of four, but on one side a bare strip is left which is formed into a canal by the large flat polyp-spicules. The locality confirms the suggestion made by Wright and Studer that this is a deep-sea species.

Locality. Laccadive Sea, 703 fath.

## Stenella sp.

The branching is fairly profuse and not confined to one plane; the axis is brown in colour and horny in testure, with a poor development of calcarcous corpuscles; the spicules are flat scales, straight or curved spindles, spindles sharply bent at an angle, and irregular spinose forms. The specimen approaches Stenella acanthina, Wright \& Studer.

Locality. Andaman Sea, 112 fath.

## Thouarella sp.

The axis is very calcareous, iridescent, longitudinally grooved; the branches arise on the two lateral faces; the stiff rigid polyps occur in opposite pairs on the branches and singly on the sides of the main stem; they are covered with flat scale-like spicules and have eight projecting spines extending considerably beyond the opercular surface; the spicules are flat, irregular, multi-tuberculate scales, many with a long smooth projecting spine; they are very like those of a Stenella. The specimen approaches Thouarella Moseleyi, Wright \& Studer.

Locality. Laccadive Sea, 703 fath.

## Family Muriceidæ.

## Paramuricea sp.

A Muriceid consisting of a simple stalk with one clavate branch. The axis is dark brown, with a lighter core; the bluntly conical verruce arise from three surfaces, those in one row alternating with those in the others. Irregularly arranged spicules cover the polyps; crown and point spicules protect the tentacles; the whole conenchyma is rough with projecting spicules-straight or curved warty spindles, tri-, quadri-, sexradiate forms, spindles with a foliar expansion on one side, and irregular forms.

Locality. Audamans, 265 fath.

Muricella bengalensis, sp. n.
A much-branched almost bushy colony of a pinkish tint, with prominent verruce which uswally arise on the lateral faces alternately and at right angles; the spicules of the verruce project at the bluntly conical apices and the colomrless spieules of the tentacles are arranged longitudinally with a basal collaret of transverse rows ; the spicules of the general ceenenchyma are straight or curved warty spiudles, dark red, light pink, or colourless.

Locality. Bay of Bengal, 88 fath.

## Muricella sp.

Another colony of a pink colour, with yellowish lateral verrucer, has the branching confined to one plane; the dark brown axis shines through the thin translucent cenenchyma.

Locality. Bay of Bengal, 88 fath.

## Family Gorgonidæ.

Callistephanus Koreni, Wright \& Studer.
This form differs from that described by Wright and Studer in not having the verrucse confined to the lateral surfaces and in showing more profuse branching.

Loculity. Andaman Sca, 238-290 fath.

## Family Gorgonellidæ.

Scirpearella moniliforme, Wright \& Studer.
An unbranched fragment may be referred to this species, with which it agrees as regards the shape of the spicules, the low verrucae, the marked grooving of the axis, and so on. It differs in having more than ten grooves on the axis, and the measurements of the spicules are nearer Sc. gracilis, Wright \& Studer.

Locality. Audamans, 270-45 fath.

## Scirpearella alba, sp. n.

A long white colony differs from $S$ c. moniliforme in having only two rows of verruce, in not having a deeply wrooved axis, in the size of the polyps, and so on. The spicules are spiny spindles, double clubs, and irregular stars.

Loculity. Bay of Bengal, 88 fath. Ann. \& Mag. N. Mist. Ser. 7. Vol. xv.

## Juncella elongata (Pallas).

Several brick-red fragments agree well with this species, but there is a trace of a longitudinal bare streak and ridge; the spicules are spiny spindles, double clubs, and double stars; no " triple stars" were found.

Locality. Bay of Bengal, 88 fath.

## Order STELECHOTOKEA.

Section I. Asiphonacea.

## Family Telestidæ.

## Telesto rubra, Hickson.

A single specimen, apparently a complete young form, with a spreading base and one branch. The polyps, which measure 2.5 mm . in height, arise at right angles to the stem and are arranged on the four sides in such a way that they scem to form a spiral. In the ridges on the axis, in the minute quantity of horny matter, and otherwise the specimen agrees with Hickson's description.

Locality. Andamans, 120 fath.

## Telesto Arthuri, Hickson \& Hiles.

A white colony closely resembling T. Arthuri, e. g. in having no grooving, in there being no axis, in the arrangement of the polyps in short spirals or in whorls and singly, and in the shape of many of the spicules-spindles straight and curved, triradiate, and quadriradiate forms. It differs in not having the secondary polyps so closely crowded. It is evidently a young form.

Locality. Station 232, 430 fath.

## Section II. Pennatulacea.

## Family Protocaulidæ.

Protocaulon indicum, sp. n.
Three complete specimens, with short thin stalk, long rachis, opposite biserial polyps, quadrangular axis, and no spicules. The larger zooids are sexually mature.

Locality. Station 239, 55 fath.

## Family Protoptilidæ.

Protoptilum medium, sp. n.
An incomplete specimen, granular in texture, with spindleshaped or rod-like, colourless, ribbed spicules, free from warts or spines. At the basal end there is a small globular swelling with very thin walls, above that there is a longer spindle-shaped swelling; from the upper end of the latter two grooves run up the rachis, one prorachidial, the other metarachidial. At the lower end of the rachis the immature polyps form a single row on cach pararachidial surface, those on one side alternating with those on the other. As the polyps reach maturity they assume a more dorso-lateral position ; they are large ( $45-5.5 \mathrm{~mm}$.), closely apposed to the stem, abruptly truncated, and the retracted tentacles form an eight-rayed star.

The specimen seems intermediate between $P$. aberrans, Köll., and P. Carpenteri, Köll.

Locality. Station 151, 142-400 fath.

## Juncoptilum Alcocki, gen. ct sp. n.

Eight unbranched fragments of an interesting new form. The white axis is cylindrical and subcylindrical ; the verruce are at first in short spirals, but alternate higher up, they coutain abundant ova ( $0 \cdot 15-0 \cdot 2 \mathrm{~mm}$. in diameter) and some flat circular embryos ( $0.52-0.55 \mathrm{~mm}$. in diameter) ; the spicules are slender fluted rods from a very pale to a deep sherry colour. Above each verruca and a little to one side there are two small oval openings; if these represent rudimentary autozooids, the specimens approach Leptoptilum, but differ in having appressed verruce without projecting spines; if they represent siphonozooids, the specimens approach Protoptilum, but differ in not having the polyps in groups of three or two. The occurrence of viviparity, as in Hickson's Gorgonia capensis, is of interest.

Locality. Station 231, 836 fath.

## Microptilum Willemoesi, Kölliker.

A complete specimen, with cylindrical axis, quadrangular to cylindrical stalk, alternate biserial zooids, needle-like spicules, and so on, is referable to this species.

Loculity. Andaman Sca, (550 fath.

556 On Deep-Sea Alcyonaria from the Intian Oiean.

## Leptoptilum sp.

Troo fragments, with quadrangular grooved axis, with biscrial alternate colourless polyps ( 7 mm . in length by 2 mm . in breadth, with cight projecting acicular points), approaches L. gracilis, but the polyps of that species are described as $3-4 \mathrm{~mm}$. in length.

Locality. Bay of Bengal, 753 fath.

## Family Kophobelemnoidæ.

Kophobelemnon Burgeri, Herklots.
A complete colony, slightly club-shaped, 57 mm . in height, agreesclosely with the description given by Wright and Studer.

Locality. Station 169, 91 fáth.

## Family Umbellulidæ.

The collection includes representatives of five or six species of Umbellela which have not been adequately studied as yet.

## Family Anthoptilidæ.

## Anthoptilum Murrayi, Kölliker.

Two incomplete specimens with the polyps all rubbed off. The pit-like markings left show that the autozooids were arranged in oblique transverse rows of two or three. The prorachidial surface is marked by a deep broad groove, the metarachidial surface by a narrow groove, so that the polypbearing surface is divided into two strips.

The specimens differ from A. Murrayi in being altogether dull white, while the 'Challenger' specimen was pale red, with brown polyps and colourless stalk. Moreover, the axis in the present specimens is more or less quadrangular, not cylindrical.

Locality. Station 10t, 1000 fath.

## Family Funiculinidæ.

## Funiculina sp.?

Twelve specimens with quadrangular axis grooved on each side, with a basal club-shaped swelling, with dark-coloured autozooids with spicular calices in groups of four, with minute white prorachidial siphonozooids. The spicules are long smooth rods with ribs.

Locality. Station 197, 400 fath.

Stachyptilum fuscum, sp. 1.
A club-shaped specimen, with autozooids arranged in ten oblique rows on each side, each row consisting of 3-1 polyps, with brown siphonozooids on the surface not occupied by the autozooids. The spicules are rod-like with jagged ends. and 4- or 5-rayed forms, some vertebra-ike. In several respects the specimen approaches St. Mucleari.

Loculity. Station 213, 137-131 fath.

## Family Pennatulidæ.

The collection also includes Pennatula Murrayi, Kölliker, and three other species, and one species of Pterocides.

> LXXIV.- Description of Acara subocularis, Cope. By C.' Tate Regan, B.A.
'Tue species described below has generally been placed in the genus Geophagus, no doubt on account of its resemblance to Geophagus cupido, Heck. This will explain its omission from my revision of the genus Acara in the April number of the 'Annals.' Mr. Rudolf von Thering recently brought me an example for identification, and when I determined it as Gerphagus Thayeri he pointed out that there was no lobe on the upper part of the anterior branchial arch. In none of the three specimens in the British Museum Collection is there any trace of a lobe on the upper part of the anterior branchial arch. Consequently this species falls in the genus Acara, and there can be no doubt that its position is next to Acara Geayi, Pellegr., which it resembles in many respects. It is worth notice that in most species of Acara the scales of the thoracic region are nearly as large as those on the side of the body, in $A$. rivulata they are smaller, in $A$. Geayi considerably smaller, and in $A$. subocularis very small.

## Acara subocularis.

Geophayus (Mesops) Thayeri (non Acara Thayeri, Steind.), Steind. Sitzb. Ak. Wien, lexi. 1875, p. 108, pl. iii. fig. 2.

LXXV.-Descriptions of Four new Loricarïl Fishes of the Genus Plecostomus from Brazil. By Rudolf von Ihering.

The fishes described below were brought by me from the Museo Paulista, São Paulo, Brazil, for comparison with the specimens preserved in the Natural History Museum. In writing these descriptions I have been helped by advice from Mr. C. Tate Regan, who has also kindly given me his authority that the species are distinct from those described by him in his Monograph of the Loricariidæ.

## Plecostomus Reyani.

Depth of body $4 \frac{1}{2}-4 \frac{3}{4}$ in the length, length of head $3 \frac{1}{3}$. Depth of head $1 \frac{2}{3}$ in its length, breadth of head $1 \frac{1}{6}$, length of snout $1 \frac{3}{4}$, diameter of eye $5 \frac{1}{2}-6$, interorbital width $2 \frac{1}{2}-2 \frac{3}{4}$. Length of mandibular ramus 2 in the interorbital width. Barbel $\frac{3}{4}$ the diameter of eye. Snout broad, rounded. Supraorbital margins not raised, supraoccipital with a very slight median elevation ; temporal plates not carinate. Scutes spinulose, the anterior ones of the two upper series weakly
carinate ; 29 in a longitudinal series, 7-8 between dorsal and adipose fin, 16 between anal and caudal. Supraoccipital entirely bordered posterionly by a single scute. Lower surface of head and abdomen completely covered with small granular scales, except for a median naked area behind the lower lip. Dorsal I 7, the first ray nearly as long as the distance from its base to the tip of snout, when laid back extending to the adipose fin; last ray $\frac{1}{2}$ as long as the first. Length of base of dorsal equal to its distance from the posterior part of the spine of the adipose fin. Anal I 4. Pectoral spine extending to anterior $\frac{1}{3}$ of ventral or a little beyond. Caudal moderately emarginate, the lower lobe the longer. Caudal peduncle $2 \frac{3}{4}-3$ as long as deep. Some rather small light spots on the upper part of head and body; dorsal brownish, with light spots posteriorly.

Two specimens, 205 and 275 mm . in total length, from the Rio l'iracicaba, São Paulo, Brazil. This species is allied to $P$. alatus, Casteln.

## Plecostomus tietensis.

Depth of body $4 \frac{3}{3}$ in the length, length of head $3 \frac{1}{3}$. Depth of head $1 \frac{2}{3}$ in its length, breadth of head 1 , length ot snout $1 \frac{3}{4}$, diameter of eye $6 \frac{2}{3}$, interorbital width $2 \frac{2}{3}$. Length of mandibular ramus $2 \frac{1}{2}$ in the interorbital width. Barbel $\frac{3}{4}$ the diameter of eye. Snout broad, rounded; supraorbital margins slightly raised; supraoccipital without median ridge, nearly flat; temporal plates not carinate. Scutes spinulose, not carinate, 27 in a longitudinal series, 7 between dorsal and adipose fin, 14 between anal and caudal. Supraoccipital bordered posteriorly by a median scute and by one on each side. Lower surface of head and abdomen naked, except for a granular strip between the bases of the pectorals. Dorsal I 7, the first ray ${ }_{5}^{4}$ the length of head, when laid back reaching a little beyond the base of the last ray, which is as long; length of base of dorsal equal to its distance from postcrior part of spine of adipose 111. Anal I 4. Pectoral extending to anterior $\frac{1}{3}$ of ventral. Caudal slightly and obliquely emarginate. Caudal peduncle 3 times as long as deep. Upper part of head with dark stripes or vermiculations; body with dark spots; fins with dark cross-bars or series of spots.

One specimen, 160 mm . in total length, from the Rio Tiete, São Paulo, Brazil.

This species is nearest to $l^{\prime}$. Vaillenti, Steind., but is very distinct.

## Plecostomus paulinus.

Depth of body $5 \frac{1}{4}$ in the length, length of head 31 . Depth of head 1 thin its length, breadth of head nearly 1 , length of snout 14 , diameter of eye 6 , interorbital width 3 . Length of mandibular ramus 12 in the interorbital width. Barbel nearly $\frac{3}{4}$ the diameter of eye. Snout broad, obtuse; supraorbital edges slightly raised; supraoccipital with slight median elevation; temporal plates not carinate. Scutes spinulose, not carinate, 25 in a longitudinal series, 6 between dorsal and adipose fin, 13 between anal and caudal. Supraoccipital entirely bordered posteriorly by a single scute. Lower surface of head and abdomen partly covered with granular scales; a median naked area behind the mouth, and a large naked area at the base of each ventral, extending forwards and confluent anteriorly with that of the other side. Dorsal I 7, the first ray $\frac{5}{6}$ the length of head, when laid back extending slightly beyond the base of the last, which is $\frac{3}{5}$ as long ; length of base of dorsal equal to its distance from posterior part of spine of adipose fin. Anal I 4. Pectoral spine extending to anterior $\frac{1}{3}$ of ventral. Caudal slightly and obliquely emarginate. Caudal peduncle 3 times as long as dcep. Uniformly olivaccous, fins dusky.

A single specimen, 160 mm . in total length, from the Rio Piracicala, São Paulo, Brazil.

Allied to $P$. lutirostris, Regan.

## Plecostomus Ilermanni.

Depth of body about 5 in the length, length of head 31. Depth of head $1 \frac{2}{3}$ in its length, breadth of head nearly 1 , length of snout 14 , diameter of eye about 6, interorbital width $2 \frac{2}{3}$. Length of mandibular ramus $1 \frac{5}{6}$ in the interorbital width. Barbel nearly equal to the diameter of eye. Snout moderately narrowed anteriorly ; supraorbital edges not raised ; supraoccipital nearly flat; temporal plates not carinate. Scutes spinulose, not carinate, 26 in a longitudinal serics, 6 between dorsal and adipose fin, 13 between anal and caudal. Supraoccipital entirely bordered posteriorly by a single scute. Lower surface of head and abdomen in great pait covered with small granular seales, with a naked area at the base of each ventral. Dorsal I 7, the first ray nearly equal to the length of head, when laid back extending a litule beyond the base of the last, which is $\frac{1}{2}$ as long; length of lase of dorsal equal to its distance from the tip of spine of adipose fin. Anal I 4. Pectoral spine bristly, extending to
anterior ${ }^{1}$ of ventral. Caudal slightly and obliquely emarginate. Caudal peduncle 2 as long as deep. 'Traces of dark spots on the upper surface of the head. Dorsal fin with the posterior part of each interradial membrane dusky.

One specimen 240 mm . in total length, from the Rio Piracicaba, São Paulo, Brazil.

This species is closely allied to P. Garmani, Regan. I have named it after my father, Dr. H. von Ihering.

## LXXVI.-Description of a new Snake from Venezuela. By G. A. Boulenger, F.R.S.

## Leptognathus latifrontalis.

Body strongly compressed. Eye large, its diameter once and a half its distance from the oral border. Rostral a little broader than deep, just visible from above ; intemasals two thirds the length of the prefrontals; frontal slightly broader than long, as long as its distance from the end of the snout, shorter than the parietals; nasal divided, the posterior part fused with the loreal, which enters the eye; a single praocular ; two postoculars; temporals $2+3$ or $2+4$; eight or ten upper labials, third, fourth, and fifth, or fourth, fifth, an I sixth entering the eye ; first lower labial in contact with its fellow behind the symphysial; three pairs of chin-shields, anterior as long as broad. Scales in 15 rows, vertebrals cnlarged and a little broader than long. Ventrals 191 ; anal entire; subcaudals 95 . Reddish brown above, with darker cross-bands broader than the spaces between them; lower parts pale brown, speckled with whitish.

Total length $800 \mathrm{~mm} . ;$ tail 220 .
A single female specimen collected at Aricaqua, 1000 m. altitude, by Sr. Briceño.

> LXXVII.-A new Cavernularid from Ceylon. By James J. Simpson, M.A., University of Aberdeen.
[Plate XVII.]
The collection of Alcyonarians made by Professor W. A. Ilerdman, D.Sc., F.R.S., in Ceylon Seas (190z) included a small specimen of much interest which was overlooked in the report by Prof. J. Arthur Thomson and Mr. W. D. Henderson
(Ceylon Reports, Royal Society London, vol. iii. 1905). The specimen dredged off Ceylon is a Cavernularid with very distinctive characters and apparently quite new to science. I am indebted to Professors Herdman and Thomson for the opportunity of studying this interesting type.

The colony shows no trace of attachment, and consists of a polyp-bearing upper portion, somewhat ovoid in shape or like a compressed cylinder with hemispherical ends, separated by a constriction from a short, compressed, relatively slender, sterile stalk or trunk, the whole presenting the appearance of a thick club with a short handle (see Pl. XVII. fig. 1). A section of the stock, whether transverse or longitudinal, has the form of a broadly terminated ellipse.

The external measurements are the following:-
(1) Total length $3 \cdot 7$, breadth $1 \cdot 7$, thickness 1 cm .
(2) Stock: length $2 \cdot 5$, breadth $1 \cdot 7$, thickness 1 cm .
(3) 'Trunk: length $1 \cdot 2$, breadth $0 \cdot 6$, thickness 0.45 cm .
(4) Constriction 0.65 cm . in breadth.

The general colour of the colony is a dark brown approaching a chocolate-colour, but when seen through a lens it seems decidedly lighter. Some parts of the trunk appear quite whitish; this is due to the spicules shining through the slightly differentiated cortical layer. Over the whole surface of the stock there are pit-like depressions into which the polyps have been retracted. Under a low-power microscope the surface presents a peculiar warty appearance, due to small hemispherical structures (groups of spicules) which are lighter in colour than the general background.

The polyps are dimorphic, the smaller siphonozooids being scattered irregularly among the larger autozooids, which are separated by distances varying from 1 to 3 mm . The autozooids are all retracted except in one small depression. The walls of the polyp-cavities seem to contract over the retracted autozooids, the cavities measuring about 0.5 mm . across, those of the siphonozooids 0.15 to 0.2 mm . The fully expanded antozooid is about 0.75 to 1 mm . in length, and the tentacles measure 0.7 mm . (see fig. 2).

The comenchyma is densely spiculate, the spicules varying greatly in form and size in the different parts. There are three distinct central canals in the stock which pass down to the very tip of the trunk (fig. 3). The spicules are arranged in bundles supporting the polyp-cavities. The larger polyps contain numerous ova measuring 0.01 to 0.025 mm . in diameter.

A summary description of the spicules is almost impossible because of the number of different forms presented in even a
small portion. They vary to a considerable extent in the different parts of the colony, but a few characteristic points. may be noted as common to all. In certain respects they resemble sponge-spicules more than the typical Alcyonarian forms, especially in the fact that they are hyaline and smooth. Many, however, bear digitiform processes, though they could in no way be termed echinulate or warty. In many cases the terminal processes do not end bluntly, but present the appearance of attached cylinders. In the bifurcated forms they closely resemble a double-barrelled gun. Another noteworthy point is the characteristic annulated structure most prominent on the cylindrical forms or those with cylindrical terminations.

A detailed examination of the spicules reveals remarkable peculiarities; those of the cortical layer of the stock are arranged in small groups, which give the colony the warty appearance already referred to. They include the following types:-
(a) Blunt spindles, $0.3 \times 0.05$ to $0.15 \times 0.05 \mathrm{~mm}$.
(b) Sinuous cylinders, $0.3 \times 0.025 \mathrm{~mm}$.
(c) Pyriform and elongated forms, $0.5 \times 0.075 \mathrm{~mm}$.
(d) Double vases, $0.3 \times 0.1 \mathrm{~mm}$.
(e) Club-shaped, with digitiform terminal processes, $0.3 \times$ 0.05 mm .
$(f)$ Others approaching a palmate form $0.25 \times 0.075 \mathrm{~mm}$. (fig. 4).
Those supporting the body-parenchyma of the stock include the following types:-
(a) Cylinders with processes at both ends, $0.5 \times 0.075$, $0.7 \times 0.05 \mathrm{~mm}$.
(b) Sinuous, with digitiform terminations, $0.5 \times 0.1,0.6 \times$ 0.075 mm .
(c) Club-shaped, with digitiform processes, $0.55 \times 0.05 \mathrm{~mm}$.
(d) Double barrels, $0.5 \times 0.05,0.7 \times 0.05 \mathrm{~mm}$.
(e) Forms like a long bone bereft of epiphyses, $0.4 \times 0.02$, $0.5 \times 0.02,0.5 \times 0.025 \mathrm{~mm}$.
( $f$ ) Irregular and sinuous forms, $0.45 \times 0.05 \mathrm{~mm}$. (fig. 5).
Those of the trunk, which are on the whole larger than those in the stock cœenenchyma, include:-
(a) Spindles, $0.8 \times 0.1,0.5 \times 0.05 \mathrm{~mm}$.
(b) Palmate forms, $0.6 \times 0.1,0.45 \times 0.05 \mathrm{~mm}$.
(c) Clubs, $0.55 \times 0.01 \mathrm{~mm}$.
(d) Cylindrical forms, $0.45 \times 0.025 \mathrm{~mm}$. (fig. 6).

An attempt to cut sections proved a failure, and it was thought undesirable to sacrifice much of the single specimen, which had already been cut into four pieces.

There seems no reon for doubt that this remark ble form is related to "C'uvernularia," e. g., in general club-like shape, distinction between stock and trunk, dimorphism of zooids, and in the alsence of spicules from the polyp-tentacles. A tabular contrast between Külliker's description of the genus and the characters of Herdman's specimen will show the distinctiveness of the latter :-
(a) Polyps 3-7 mm. in length.
(b) Axis small or abseut.
(c) Spicules long and slender, also slightly flattened.
(d) Stock and trumk cyliudrical.
(e) Stock and trunk continuous.
$(t)$ Four canals in trunk and stock well developed.
(a) Not exceeding 1 mm.
(b) Axis absent.
(c) Besides the long and slender forms, which show no trace of flattening, there are very numerous short broad forms of very diverse shapes.
(d) Rather elliptical.
(e) Separated by a constriction.
(f) Three canals in the stock, which become less distinct, almost appearing as two in the trunk.
(g) Zooids not so numerous as in Kölliker's description.
'Thus IIerdman's specimen differs from Cavernularia in the length of the autezooids, in the frequency of the siphonozooids, in the shape and character of the stock and trunk, in the rumber of longitudinal canals, and in the details of spiculation. Although Cavernularia obesa is a variable form, none of the varieties present any close resemblance to our specimen. It also differs from C'. madeirensis (Studer) both in the size and frequency of the zooids. The genera Stylobelemnon (Kölliker) and Stylobelemnoides (Thomson and Henderson) need not be considered.

- It seems necessary, therefore, to establish a new genus in the subfamily Cavernularidæ, and it is interesting to note that the Ceylon collection included another new genus (Stylolelemnoides) also in the same subfamily. I propose to nane the new form

> Fusticularia Ilerdmani, gen. et sp. n. (Pl. XVII.)

A sonewhat sponge-like Cavernularid with a flattened ovoid stock separated by a constriction from a comparatively slender sterile trunk; with dimorphic retractile polyps, the autczooids not exceeding 1 mm . in length, the much smaller siphonozooids scattered irregularly among the autozooids; with abundant densely spiculate cocnenchyma, traversed by three longitudinal central canals passing down into the
trank; with smooth hraline spicules bearing peculiar Gigition terminal proceses and whowing very characteristie anmulations, especialls near the ends.

Lacality. Cheval Par, S.E. of Ceylon, 6 fathoms.

LXXVIII - Natural History Netes from the R.I.M.ミ. Ship 'Incestigator,' Capt. T. H. Heming, R.N., commanding.Series III., No. 9. On a nevo Species of the Dorippoid Genus Cymozomus from the Andaman sea, considered with reference to the Distriturtion of the Durippidx ; with some Remarks on the cullied Genus Crmonomops. Br. A. Alcoce, M.B., LL.D., F.R.S., Superintendent of the Indian Museum and Professor of Zoology in the Medical College of Bengal.

> Plate XIIII-
> Contents.

1. Cymoromus and the Dorippide.
2. Cymonomnes cheracterized, and C: andamanicus distincuibbed and diffrrurtiatel
3. Gengrapzical Dietribution of Cymonornus and other Dorippoid

4. Themerlis on the Gunus Cymonomope.
5. List of the Lorippida.

## 1. Cthonomes and tee Dorippide.

The small thind decp-sea crabs of the genus Cymonomus have, in the ' (Qarterle Jourtal of Microscopical Science' for Decemiter 190.\%, forretid the subject of a paper, br Professor Ras Lambeser, of much interest both biological ard taxonoraic: so that the diocorery of a rerresentative of the gerave in the Andaman Sea mar, perhaps, be thought worthy of iddependent notice, erpecially as it inrites zoogeographical inquiries that seem to deserve consideration.

Cymonomus betongs to the Osystome family Dorippidxa primitive fanilo. in the trpical members of which, as in
the still more primitive Dromiacea, the separation of the orbital and antennular fosse is very incomplete, and the antenna is large and the elements of its peduncle are unusually distinct ; and in which also, as in many of the Dromides, the last two pairs of thoracic appendages are subcheliform and reduced in size, have a strong dorsal elevation, and are often used for holding some lind of protective covering-such as a valve of a Lamellibranch shell, a wormtube, a water-logged picce of drift vegetation, or sometimes an inert commensal-over the back, the habit indicating a passive disposition and a sceluded life.

The family Dorippidre at present embraces 10 genera and perhaps 50 recent species, many of which, in conformity with a well-established " law" applicable to primitive forms, have been driven into the depths of the sea.
[I must here remark that I do not include the genus Palicus, Philippi (=Cymopolia, Roux), with the Dorippidæ, although it was so placed by H. Milne-Edwards and is so retained by Bouvier. Palicus seems to me to be an aberrant Grapsoid. It may be added that this exclusion in no way affects the question here considered, since in the matter of geographical distribution Palicus presents no points of disagreement.]

## 2. Cyuononus characterized, and $C$. andajanices distinguisiled and differentiated.

Chonomus, A. Milne-Edwards.
Cymonomus, A. Milne-Edwards, Bull. Mus. Comp. Zool. Harvard, viii. 1, 1880, p. 26; Milne-Edwards is Bouvier, Crust. Décap. 'Hirondelle ' (Monaco, 1894), p. 57, and Mem. Mus. Comp. Zool. Harvard, xxvii. 1, 1902, pp. 72, 80 ; Bousier, Bull. Soc. Philom. Paris, (8) ix. 1898, p. 59 ; Young, Stalk-eyed Crust. W. Indies, \&ce. 1900, pp. 321, 323 ; Lankester, Quart. Journ. Micr. Sci., Dec. 1903, p. 430̃.
Carapace square or squarish, not concealing the anterior segments of the abdomen; with the regions faintly defined, except the cardiac and postgastric, which are very distinct.

The front forms a rostrum, and the orbito-antennal border is prominent beyond the antero-lateral angles of the carapace; apart from this there are no indications of orbits or antennular fosse.

The eye-stalks are either fixed or have their mobility diminished, and the eyes are unpigmented and vestigial.

The antennules are large and unconccaled. The antennal peduncle is not hidden and its renal tuberele is particularly prominent.

The buceal cavern is large and square ; its roof is high
and is not well differentiated from the receding epistome, so that in an end-on view it is widely open, although ventrally it is closed by the external maxillipeds. The efferent branchial channels are separated, so that the endopodite of the first maxillipeds (which is so much produced in typical Oxystomes, where the channels lie side by side in the middle line of the palate) is of no great length, being much shorter than the exopodite.

In the first maxillipeds the epipodite is well developed, in the second it is almost vestigial, and in the third (external maxillipeds) it is small.

The external maxillipeds, though the ischium and merus are rather narrow, almost cover the buccal cavern ventrally, extending beyond the base of the antennal peduncles. The merus is produced far beyond the carpal articulation, so that it is not much shorter than the ischium. The flagellum is large, coarse, and completely exposed. No afferent branchial fissure is apparent between the carapace and the base of the chelipeds, this area being completely closed by the coxa of the external maxillipeds.

The chelipeds are equal, much shorter, and in the male considerably stouter, than the true crawling-legs.

The first and second pair of true legs are very long, especially as to the dactylus, and are somewhat compressed; the third and fourth pair are short, and in claw-like dactyli, and have the dorsal elevation usual for the family.

The abdomen is large, its breadth, even in the male, corresponding with that of the thoracic sternum ; all its segments are distinct, and the three anterior ones are visible in a dorsal view. In the male there are two pairs of large abdominal appendages modified for sexual purposes; in the female, according to Bouvier, there are only three pairs of abdominal appendages.

The oviducts, according to Bouvier, open on the coxæ of the second pair of true legs.

The branchial formula given by Bouvier for the European and West Indian species, to which also the Indian species conforms, is as follows :-

| Somites and their appendages. | Podobranchir. | Arthrobranchir. | Pleurobranchiæ. | Total. |
| :---: | :---: | :---: | :---: | :---: |

## Cymonomus andamanicus, sp. n. (Plate XVIII.)

The entire surface of the body and of all the exposed parts of its appendages, except the terminal joint of the antennular peduncles, is finely frosted.

Carapace slightly, though manifestly, broader behind than in front, without any marginal spinules; the lateral borders are ill-defined posteriorly, and the posterior border is coneave in the middle line; the usual regions and furrows are rather faintly indicated.

Rostrum triangular, acute, reaching to the middle of the eye-stalks: the frontal border on either side of it is advanced beyond the antero-lateral angles of the carapace, but the subantennal tooth, which is so conspicuous in C.guedratus, is small and quite invisible in a dorsal view, though plain enough in a side view.

The eye-stalks, which are rigidly fixed, divergent, and slightly curved, are deroid of hairs and enlarged spinules and do not reach the tip of the antepenultimate joint of the antemal peduncle ; the cye is a small, smooth, unpigmented, subterminal patch.

The antemules are stout, and their peduncle is more than three-fourths the length of the carapace.

The antenne are shorter and slenderer than the antenmules; their peduncle does not reach the terminal third of the second joint of that of the antennules, and none of its joints are spinose; their lash is rather more than half the length of the carapace.

The gap betwcen the epistome and the anterior end of the extemal maxillipeds is singularly wide and almost subtubular; on either side of the epistome is a spinule which may, perhaps, serve to separate the inhalant from the exhalant currents. The epipodite of the first maxillijeds is broadly foliaceous.

The chelipeds of the male are equal, about half again as long as the carapace, and not very massive; a spinule at the inner angle of the wrist and a few on the upper border and outer surface of the hand are enlarged ; the hand is longer than the ischium and merus combined, the fingers are slightly longer than the palm and their cutting-edge is entire.

The first pair of true legs are about 3 times, the second pair about 3 童 times the length of the carapace ; their dactyli are subfalcate, that of the first pair contributing decidedly less, and that of the third pair a little more, than one third the total length of the appendage. The third pair of legs
are about once and a half, the fourth pair about once and a quarter, the leugth of the carapace, the dactylus in both having the form of a small claw.

The length of the carapace is 85 millim., the breadth posteriorly 8 millim., and the breadth across the anterolateral angles 7 millim.

A single specimen was taken just inside the Andaman basin, at 'Investigator' Station 32:2: lat. $11^{\circ} 26^{\prime} 39^{\prime \prime}$, long. $92^{\text {c }} 53^{\prime} 45^{\prime \prime}$, depth 378 fathoms; bottom green mud with Foraminifera. Unfortunately the bottom-temperature was not recorded, but from previous observations we can infer that it was between $47^{\circ}$ and $48^{\circ}$ Fahr.

The chicf differences between C. andamanicus on the one hand and the Atlantic species C. gramulatus and C. quadrates on the other are as follows :-

The carapace is less square, its lateral borders being distinctly, if slightly, convergent anteriorly; its cervical and branchial grooves are somewhat fainter dorsally; and there are no spines at its antero-lateral angles. The rostrum also is broader and much less prominent.

The eye-stalks are quite immovable, and, though microscopically granulose, are not at all spinous.

The cutting-edges of the fingers of the chelipeds are not scrrated, but, to the naked eye, are quite entire.

From C. gramulatus the present species is further distinguished by the much smaller subautennal tooth at the outer angle of the buccal cavern; and from C. quadiatus by the fact that the outer border of the antepenultimate joint of the antennal peduncle is not sharply serrated.

## 3. Geographical Distribution of Cfagononus and other Dorippoid Genera.

The singular sort of residual distribution of Cymonomus requires to be explained, but as it fairly well exemplifies that of the family, it may be considered with that of all the other genera of the group, in the way that the subject has already been presented by lrofessor Boxvier, in his paper on the classification, origin, and distribution of the family, published in the 'Bulletin de la Société Philomathique de Paris' for 1896-1897, pp. 67-69.

1. Dorippe, Fabr.-This genus, which is composed of 12 or 13 recent species, belongs to the fauna of the shallow water, not having hitherto been found outside the 60 -fathom line. Its headquarters appear to be in South-castern and

Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.

Bastern Asia, from the Bay of Bengal to Japan and Australia. On the other hand, two species occur in the Mediterranean, and one off the West Coast of Africa (Cape Verde to the Congo). One of the commonest Indo-Pacific species (D. dorsipes, L.) is also met with off the east coast of Africa.
9. Efiusa, Roux.-This genus consists of 14 species, and though fonnd in the Mediterranean and in some parts of the Western Hemisphere, in quite shallow water ( $13-2$ (f fathoms), commonly lives far down the submarine slopes between 200 and 1200 fathoms. The species are found off the west eoast of Tropical America, from the Gulf of California to the Cocos Hands (Panama): in the region of the Gulf of Mexico, from Florida to the Antilles, and also further north off the south coast of New England ; in the Eastern Atlantic in the neighbourhood of the Azores and Canaries ; in the Mediterrencan Sea and its Atlantic gate ; and in Oriental Seas, from the Arabian Sca to Fiji.
3. Ethusina, S. I. Smith.-Seven (or six) species are included in this genus and, among crabs, ther are the decpest dwellers of any known, going down to abysses of nearly 2200 fathoms, althoughone-E. Smithiana, Faxon-has been taken in 134. fathoms. They have been dredged off the tropical Pacific coast of America, between the Galaparos and Cocos and the mainland ; off the east coast of the Northern United States of America, as far as $38^{\circ} 53^{\prime} \mathrm{N} . ;$ in the neighbourhood of the Azores, of the western coast of Morocea, and of the Cape Verde Islands ; in the Arabian and Andaman Seas, and in the depths of the land-bound basins of the East Indian Archipelago; and off Japan, in $34^{\circ} 37^{\prime}$ N. According to Faxon, two of the Eastern Pacific species are identical with two from the western confines of the same ocean.
4. Tymolus, Stimpson, is represented hy a single species found in shallow water off Japan, about lat. $42^{\circ} \mathrm{N}$. The genus is imperfectly known, bat it appears to connect Dorippe and Ethusa with C'yclodorippe and Cymonomops.
5. Cyemonorippe, A. Miluc-Edwards.-This genus for the present embraces fivesublittoral species, of which three occur in the West Indian region, from Florida to Trinidad, in 50 to 357 fathoms, while the other two are found in Japan between 35 and :00 fathoms. According to Bonvicr, two of
the species referred by their authors to this genus-namely, C. dromioides, Ortmann, from Japan, and C. gramilata, Rathbun, from off the island of Trinidad-may possibly belong to the next.
6. Clithrocerus, Bouvier, at present stands for two species from the West Indies and adjoining coast of North America as far as $32^{\circ}$ N., and inhabiting the sublittoral zone at a depth of 50 to 262 fathoms.
7. Cymononus, A. Milne-Edwards.-Perhaps six species may be assigned to this genus, their bathymetrical range being from 101 to 1380 fathoms. Their area of distribution includes the Caribbean Sea, the eastern part of the North Atlantic from Iceland to the Arguin Bank off the Sahara (about $21^{\circ} \mathrm{N}$.), the western part of the Mediterranean Sea, the east coast of Equatorial Africa, and the Andaman Sea.
8. Cymopolus, A. Milne-Edwards, includes two species, one from 75 fathoms off the coast of Florida, the other from the West Indies (Montserrat), 148 fathoms.
9. Coryconus, A. Milne-Edwards, receives a single species from the Went-Indian region and dredged in $175-250$ fathoms.
10. Cymonomops, Alcork, rests upon a single species found in the land-locked basin of the Andaman Sea at 265 and 40 fathoms.

The foregoing summary of the facts of distribution seems to me to support the opinion of Bouvier that the family Dorippidx "appears to have had its centre of origin and dispersal in the Caribbean region." It further seems to suggest an answer to the question whether the dispersion has been westwards by way of the Pacific or eastwards by way of the Atlantic. Of any emigration westwards through the Pacific we find very little evidence, while in the other direction the grouping of the family, on the one hand, in what may roughly be call d the Panama and West-Indian region, and, on the other hand, in the seas of the Oriental region (India to Japan and Australia), with a halfway-house in the eastern part of the North Atlantic and the Western Mediterranean, seems capable of only one interpretationnamely, an open-sea connexion in the direction indieated by
the halfway-house at a time when the primitive crabs, which are now represented by a furtive remnant, were a more flourishing stock.

I may mention that this interpretation is confirmed by the distribution (tabulated in my 'Catalogue of Brachyura Primigenia in the ludian Musenm') of three other families af pimitive crabs, namely the Homolodromide, the Homolidee, and the Latreillide; and though I must add that it finds no particular corroboration in the distribution of the 1)ynomenider and 1)romide (which are also primitive groups related to the Ifomolidae), I may suggest, as a necessary explanation, that the Dynomenide and Dromide are very largely shallow-water and littoral forms, whose distribution may have siuce been influenced by causes which would not affect species that had become adapted to deep-sea conditions.

I may also refer for corroborative evidence in this connexion to my paper in the 'Amals' for October 1904 on the distribution of the Amphibians of the family Cacilidde, in whichalso the suggestive geographical relations of the Indian sublittoral Paguride are tabulated.

## 4. Remaris on the Genus Cymonoyops.

In the 'Bulletin de la Société Philomathique de Paris,' 8 sér. tom. ix. (1896-1897), and again in the Report on the Dromiacea and Oxystomes dredged by the 'Blake,' published in 1902, Professor Bouvier, who conld not have scen my paper on Indian Oxystomata, published in the 'Journal of the Asiatic Society of Bengal' for 1896, complains that the affinities of (ymonomops lave not been made clear; so I take this opportunity of re-characterizing this genus and of adding the necessary information regarding the structure of its mouth-parts, the distribution of its gills, and the position of the openings of the oviducts.

> Crmonomors, Alcock.
> ('ynomomops, Alcock, Aun. \& Nag. Nat. Hist., May 1894, p. 406, and Journ. Asiatic Soc. Bengal, vol. lxv. pt. 2, no. 2, 1896, p. 286; Bouvier, loc. cit.
> Carapace almost semicircular in outline, not concealing the anterior abdominal terga, its grooves and regions fairly well defined.
> The front consists of a narrow rostrum, not much breaking the general contour of the carapace and ending in two teeth,
between and beyond which can be seen, in a dorsal view, the roof of the much-produced efferent branchial canal. On either side of the rostrum are two teeth which form the dorso-lateral walls of the common orbito-antennular fossæ.

The eye-stalks are slender and freely movable; the eyes are almost without pigment.

The antenules, which are larger than the antenne, are not entirely concealed in flexion.

The buceal cavern is of great length, its median efferent branchial canal, which is remarkably well defined, being prolonged anteriorly over the epistome and beyond the rostrum ; it is closed veutrally and anteriorly, except as regards the tip of the branchial canal, by the long narrow external maxillipeds.

In the external maxillipeds the merus is about three fourths the length of the ischium, the flagellum (which is completely exposed) articulates near the middle of the merns and well inside its edge, the exopodite (which is broad and nonflagellate) is hardly longer than the ischium, and the epipotite is absent or minutely vestigial.

In the first maxillipeds the endopodite is nearly twice as long as the exopodite and is produced as far as the end of the efferent branchial canal, to which it forms a floor, as in typical Oxystomes; and the epipodite is large and foliaceous.

In the second maxillipeds the exopodite has the form of a lash and is much longer than the endopodite, and the epipodite also is of great length.

No afferent branchial fissure is visible between the carapace and the base of the chelipeds.

The chelipeds are equal and are much shorter, and in both sexes much stonter, than the legs.

The first and second pairs of true legs are stoutish and are of very great length, especially as regards the merus. The third and fourth pairs of legs are short, almost fitamentous, and have the usual dorsal elevation.

The abdomen in the male is small, is not so broad as the corresponding part of the thoracic sternum, and carries two pairs of large appendages modificd for sexual purposes ; in the female it is large and broad and carries four pairs of appendages; in both sexes only six segments are distinguishable.

The oviducts open on the coxac of the second pair of true legs.

The branchial formula is as follows:-

| Somites and their appendages. | Podobranchice. | Arthrobranchice. | Pleurobrauchise. | Total. |
| :---: | :---: | :---: | :---: | :---: |
| VII. (1st maxillipeds). | epip. (large) | . . | . . | epip. |
| VIII. (2nd , ). | epip. (large) | $\cdots$ | $\ldots$ | eprp. |
| IX. (3rd ", ). | - | 2 | . | 2 |
| X. (chelipeds) .... | . . | 2 | . | 2 |
| XI. (1st true legs).. | . | . | 1 | 1 |
| XIL. (2nd " ") .. | . | . | 1 | 1 |
|  | 2 epip. | 4 | 2 | $6+2$ e |

In addition there are two microscopic filaments, pr bably the vestiges of a podobranch and arthrobrauch, on somite VIII.

The genus is represented by a single species (which has been described in the 'Annals' and 'Journal' above cited, and figured on plate xiv. of the "Illustrations of the Zoology of the 'Investigator' '') from the Andaman Sea, 2605-405 fathoms.

## EXPLANATION OF PLATE XVIII.

Fig. 1. Cymonomus andamunicus, male; enlarged three times.
Fig. 1 a. The same; rentral view of anterior part of cephalothorax and carapace, showing the buccal cavern almost cumpletely closed by the external maxillipeds and the absence of any afferent branchial opening between the carapace and the base of the chelipeds: enlarged four times.
Fig. 1b. The same; end-on riew of the animal, showing the graat breathing-opening between the front of the carapace and the anterior border of the external maxillipeds; enlarged fuur times.

In concluding this paper I have to express my thanks to Professor E. L. Bourier for his kinduess in sending me specimens of Cymonomus gramulatus (Norman, for comparison with the new Andaman species.
LXXIX. - Observations on Coleoptera of the Family Buprestidk, with Descriptions of new setecies. By Chas. O. Waterhotse, F.E.S.
[Continued from rol, siv. p. 342.]
Aycocera Fenyesi, Kerr.
The type of this species is a rather small example of A. gentilis, Horn. The specimen labelled A. gentilis in Capt. Kerremans' collection is A. gigas.

## Hypoprasis maynifica, Phil.

Capt. Kerremans gives this as a srnonym of H. huipogn, Fairm. (Wytsman's 'Genera,' p. 67,. I have not leenable to see the description of this species, but the specimens received by the Museum with this name differ from H. harpago, Fairm., in having the sides of the thorax coppery, and the posterior angles more rugosely punctured. The elytra are less acuminate. I think it is a distinct species.

Halecia soror, sp. n.
Fuscoreneous, shining. Head concave in front, and deeply longitudinally canaliculate; the clypers coppery.

Antenne greenish blue. Thorax one quarter broader than long, obliquely narrowed in front, almost rectilinear at the middle (not angulated), slightly sinuate before the posterior angles, which are only very slightly or scarcely divergent. The disk is longitudinally, moderately strongly impressed, with a sharply defined central impressed line extending from the front margin to the basal round fovea. The punctuation on the disk is "oderately fine and not very close; at the hind angles it is stronger but not closer ; the area of the anterior ang'es is closely and rather strongly punctured. The elytra at the humeral callus are only slighty wider than the thorax, but gradually widen for three fifths their length, and then narrow to the apex ; the apices very acute. Each elytron has a very slightly raised obtuse costa near the suture; a second extending from the shoulder joins the first near the apex; a third rery olscure one commencing below the shoulder ; and the usual sublateral one. The third costa has a very slight interruption about the middle, and behind the middle it is interrupted by a moderately large but very shallow impression.

Long. 21-26, lat. $7-9 \mathrm{~mm}$.
Hab. Ecuador, Balzar (Buckley).
This species is near H. rugipennis, L. \& G., but rather differently coloured. The thorax is straighter at the sides, and the discoidal impression is of more uniform width, and the median line is very distinct and extends the whole length.

## Halecia auropunctata, Kerr.

There is a specimen in the Museum from Bogota which has scarcely any trace of the spots on the elytra so conspicuous in the type specimens of this species.

## Halecia trilineata, sp. n.

Closely allied to H. octopunctata, Fabr., and H. decemimpressa, Saund. Above obscure purple ; below bright golden green. Head very closely and finely punctured; with a narrow green line bordering the eyes, widening somewhat on the lower part of the face; there is a short, slightly impressed median green line above the clypens. Thorax convex, narrowed towards the front, the sides rectilinear; the surface is rather closely punctured, the punctures rather stronger and rather more asperate than in H . 10 -impressa. There are three green lines as in that species, but they are scarcely impressed. There are two small impressions near
the base, one on each side of the sublateral green line, placed obliquely. The margin is green. The anterior area between the green line and the margin is somewhat swollen, and the punctuation here is distinctly less close than in H. 10-impressa. The elytra have the lines of punctures quite distinct, much more so than in $H$. 10-impresse. Each elytron has the following golden-green marks:-a short stripe near the scutellum ; a basal fovea; a streak below the humeral callus ; a moderately large impressed ovate spot on the disk at one-third from the base, and immediately above this there is a short oblique streak; a fine, scarcely noticeable streak above the sublateral carina, almost miting with the spot below the humeral callus; a large, transverse, impressed spot at one third from the apex ; a stripe at the suture at the apex; the extreme margin is very narrowly edged with green. Tibiæ cyaneous.

Long. 16, lat. 6 mm .
Hab. Mexico.
Halecia elonyata, sp. n.
Very elongate and narrow. Purple-coppery, reflecting green shades in certain lights; smooth, shining; below æueous. Head very densely and rugosely punctured in front, the punctures slightly separated on the vertex. Thorax purple with green sides ; broadest rather behind the middle, slightly narrowed in front ; gently sinuate before the hind angles, which are acute. There is a distinct clongate impression in the middle of the base. The punctures on the disk are very distinct, variable in size, not very close together; at the sides they are closer, and are slightly crowded at the front angles. Elytra rather deeply striated, the strice rather strongly and closely punctured; the interstices gently convex, smooth; the sides rather closely but vaguely punctured. The marginal serration is strong and acute. The apex of each elytron is emarginate, the sutural and onter teeth thus formed nearly equal. Femora æneous-black. Tibire and tarsi ferruginous, slightly pubescent. Antemne reddish brown, long, the third to seventh joints very elongate. Abdomen in the middle finely punctured, the punctures not very close together; at the sides the punctuation is finer and much closer, with fine pubescence.

Long. 19, lat. 6 mm .
Hab. Ecuador, Chiguinda (Buckley).

## Halecia Buckleyi, sp. n.

Elongate, rather narrow, above viridi-mncous, below
brunneo-iencous, shining. Head densely and rugosely punctured in front, the punctures slightly separated on the vertes. Thoras broadest behind the middle, slightly narrowed in front, scarcely sinuate betore the basal angles, which are slightly acute, but not prominent ; the sides ver! gently arcuate. link with a distinet but not very deep longitudinal impression extending from the base to the front margin. The punctures on the disk are distinct, not very close togetier; at the sides they are clower and stronger, and are somewhat crowded near the front angles. There is a deep forea at the base, near the pastenior angle. The elytra strongly punctatestriate, the strice rather deeply impressed near the suture, the interstices convex near the suture, less so laterally, the sceond and fourth costiform at the apex. There is a shallow, wrinkled impression at the base; a moderately large, distinet, oblique, reniform impression at the middle; and another transversely ovate one halfwat between this and the apex The apex of each elytron gently emarginate, the sutural and lateral teeth subequal. Femora blackish eneous, shaded with purple at the apex. Tibire and tarsi ferruginous, with rery shont pubescence. Antenne obscure reneous, the third joint very long, the fourth rather shorter, the following Eradually decreasing in length. Abdomen in the middle finels punctured, the punctures not very close together; at the sides the punctures are very fine and much closer, with some fine pubescence.

Long. 14-22, lat. $4 \frac{1}{2}-7 \mathrm{~mm}$.
Hub. Ecuador, Sarayacu, and Chiguinda (Buckley).
The small specimen, which is a male, is more golden green below, with coppery shades, and the femora are green.

## Halecia sexcostata, sp. n.

Form of the preceding, brownish æneous above and below, shining. Head closely and rather rugosely punctured in front, the punctures slightly separated on the vertex. Thorax shinius, slightly narrowed in front, the sides gently arcuate, very slightly simuate before the posterior angles, which are somewhat acute. The disk with a not very deep longitudinal impression extending from the base to the front margin. The surface on each side of this with distinct but rather small punctures, which are rather widely separated; towards the sides the punctures are somerthat stronger and crowded, the intervals having a tendency to form short oblique ruge. There is a fovea at the base near the posterior angle. The elytra strongly punctate-striate, the second, fourth, and
sixth interstices costiform: the first costa becomes wery fine at the apex; the second extends from the lumeral callins to the outer apical tooth; the third is abbreviated at each end. The apes of each elytron is rather deeply emarrinate, and the two tceth thus formed are very acute. Tibise shaded with steel blue, slightly pubecent. Tarsi ferruginous, i,ut more or less metallic green above. Abdomen in the middle more stroagly punctured than in the preceding species, the punctures slighty elongate ; at the sides the punctuation is very fine and rather close. The pubescence is catremely short. $\circ$.

Long. 20, lat. $6 \frac{1}{2} \mathrm{~mm}$.
Hab. Bogota.
A single specimen preseuted bṛ Señor José Vergara, F.Z.S.

## Halecia ruyosa, sp. n.

Elongate-elliptical, blackish reneons abore, dark tenems below, moderately shining. Head very closely and rather strongly punctured, tilited with steel-blue, with a lightly impressed median line. Thorax moderately narrowed in front, broadest just behind the mildle. almost straight the the posterior augies, which are acute and slightly prominent. Disk with a rather strongly marked impression extending from the base to the aper; it is rather broad at the base, narrowed in front, with a short smooth line in the middle, on each side of which is an irregular line of strong punctures. The punctures ou the disk are small but very distinct, not very close together, at the sides ther are rery deep, larger, and at the anterior angles often confluent. The surface is very uneven ; the anterior margin is impressed, and there is a small forea at ti.e base near the hind angles. The elytra are at their base distinctly bruader that the thoras subparallel for two thirds their length. and then narrowed in the usual way to the apex. They are very deeply punctate-striate, or rather there are lines of deep foveæ, the foveæ being of unequal size, and sometimes two or three unite into one; the second interstice is slightly costiform, the others are narrow and rendered irregular by the strong forex. The aper of each elytrou is emarginate, the outer tooth rather less acute than the sutural one. The abdomen is more strongly and rather more closely punctured in the middle than in the preceding species; at the sides it is closely and finely punctured, the punctures being slighty as, erate. Tarsi blui-h green. Autenne almost black; the second joint rather short, the third about one third lomeer, the fallowing rather shorter and widened towards the aper.

Long. 18, lat. 6 mm .
IIal, Amazons, Barreirao de Monte Alegre, Nov, 1873.
I single example collected and presented by Prof. Trail.

## Halecia viridisplendens, sp. n.

Bright golden green, shining. Ifead densely and modelately strongly punctured, with an impressed median line extending almost to the vertex. Thorax obliquely narrowed in front, broadest at one third from the base, somewhat angularly emarginate before the posterior angles; the sides slightly angular at the broadest part, with the margin slightly thiekened at this part. Disk tinted with darker bluish green, with a little purple near the hase; the darker portion finely, distinctly, but not very closely punctured; the anterior part of the margin and all the region of the anterior angles very closely and more strongly punctured, the closely puotured surface extending along the front margin. There is a shallow lout distinct median golden line which is impressed posteriorly. There is a round puncture at the base, rather nearer the posterior angle than the middle, and this is extended forward by a slight impressed punctured line as far as the middle. The sides are slightly impressed above the lateral angulation. The elytra are scarcely broader than the thorax. Each elytron has a slightly raised obtuse costa near the suture, of a slightly darker or more coppery hue than the impressed parts, but at the point where it diverges at the base there is a small green spot. There is another slightly sinuons costa extending from the humeral callus to the apex, of unequal width, and with a small green spot on the middle. There is a third costa arising below the shoulder and joining the second at a short distance from the apex ; this is interrupted by two small green spots. Wach costa has an irregular line of punctures on each side of it. The interstices are convex in the middle, the second and third each haring two small green spots. The apices are very acute, each being slightly and obliquely truncate on the inner side. Tarsi tinted with eyancous. Abdominal segments shaded with coppery golden at the base.

Long. 23, lat. 7 mm .
Hab. Brazil, Joinville.
This species closely resembles $H$. chrysodemoides, Saund., but differs from it in having the thorax angulated at sides; the punctuation on the disk is finer, and closer at the anterior angles; there is an impressed longitudinal line at some distance from the side; and the apices of the elytra are much more acute.

Iridotemia javana, Kerremans.
The type specimen of this species agrees woll with one in the Maseum collection labelled by Saunders "lineata, Deyr., compared with type."

Chrysodema navicularis, Kerr.
This is the same as C. ventralis, Waterh., which has priority.

## Chrysodema Fairmairei, Kerr.

In Wytsman's 'Genera,' p. 74, Capt. Kerremans has sunk this species as a synonym of C. Mniszechi. This is an error. It is really a synonym of C. Dohroii, Saund. (Mindanao). (. Mniszechi. Deyr.. has the thorax less elosely punctured; it ocenrs in Goram and Cesam.

Chrysodema sumatrensis, Kerr.
I doubt if this is distinct from C. Wallacei, Deyr. Capt. Kerremans appears not to have known Wallacei; the specimen in his collection so named was Mmiszechi, Deyr.

Chrysodemu Yerburyi, sp. n.
Elongate, elliptical, not very convex, golden green. Thorax gently convex, slightly narrowed in front, closely puncturel, the punctuation more dense and finer at the sides than on the disk; the median raised line scarcely noticeable. There is a slight round impression near the side, a little behind the middle. Elytra only a very little wider than the thorax, gently and erenly convex, green with a slight coppery shade. Rather closely and moderately strongly punctured, the punctures meven in size and quite irregular ; near the base the punctures are rather stronger and are transrerse, the intervals forming transerse rugie. The coste which are seen in C'. auroplagiata and many other species are only seen in this species at the apex in the form of a $y$. Near the margin there is a finely punctured brassy impression, extending from the apex for two fifths the length of the elytra. Prosternum slightly convex, moderately strongly and not very thickly punctured. Antemas black. Legs rather bluish green.

Long. 28, lat. 10 mm .
Hab. Ceylon, Trincomali (Yerbury).
This is quite unlike any other species of this genus known to me.

Closely allied to C/urysodema, but differs from all the species of that gemus in having two sharply cut impressions at the base of the thorax. Just below the shoulders the elytra are acutcly angular. The tarsi are yellow.

1 propose this for the insect 1 formerly described as Pssudochrysodema (:) Walkeri (Amu. \& Mag. Nat. Hist. 1892, x. p. 411).

Capt. Kerremans has more recently deseribed it as Chrysodema cupriventris.

## Thimedes, gen. nov.

Closely allied to Chrysodema, but with a form and appearance which are suggestive of Psiloptera. Thoran evenly convex, without impressions, but with a slightly raised median line. The marginal carima extended to the anterior angle. Jilytra strongly striato-punctate; the apical margius scrrate. Antemne yellow. Tarsi metallic. Metathoracic episterna gradually acuminate posteriorly.

I propose this generic name for Chrysodemu fluvicornis, Saund.

The only Chrysodema known to me that at all resembles this is C. hebes, Kerr., but neither in that nor in any other species does the lateral carina of the thorax extend quite to the anterior angles as in flavicornis.
[To be continued.]
LXXX.-New Neotropicul Mulossus, (omepatus, Nectomys, Procchimys, and Agouti, with a Note on the Genus Mesomys. By Oldefeld Thomas.

> Molossus Burnesi, sp. n.

Allied to the very small species of Molossus, M. tropidorhynchus, Gray, and M. pygmens, Miller, but distinguished by the different shape of the brain-case.

Size about as in M. tropidorhynchus and pygmeeus, markedly less than in M. obscurus, of which there are two specimens in the same collection. Hairs of back exceedingly short, less than 2 mm . in length, as against 3 in $M$. obscurus, their bases white and their tips brown, the net restilt being a
lighter colour than in M. obscurus. Belly paler brown, approaching "broccoli-brown." Muzzle not so high anl not so conspicuously ridged as in M. obscurus. General characters of ear, tragus, \&c. as in other members of the group. Hind legs markedly shorter than in M. obscurus.

Skull, as compared with that of M. tropidorhynchus, which it about equals in siz:, remarkable fur its large, rounded, and inflated brain-case; anteriorly the brain-case bulges out over the temporal fossa much more than in the allied species, and the upper part projects laterally beyond the lower. In consequence the greatest brealth of the brain-case has to be taken high up on the skull, and not at the base of the zygomata, and is equal to the same dimension in the much larger M. obscurus.

Teeth apparently much as in N. tropidorhynchus; upper incisors not quite tonching canines ; anterior lower premolar little more than half as broad as the posterior.

Dimensions of the type (measured on the spirit-specimen):Forearm 33.7 mm .
Head and body 53 ; tail 31; third finger, metacarpus 35, 1st phalanx 16 , 2nd phalanx 15 ; fith finger 33 ; lower leg and foot (c. u.) $19 \cdot 5$.

Skull: greatest length 16.2 ; basal length 12 ; zygomatic breadth 10.7 ; interorbital breadth 3.9 ; breadth of braincase $8 \cdot 9$; mastoid breadth 10 ; front of canine to back of $m^{3} 6$; front of lower canine to back of $m_{3} 6 \cdot 7$.

Hab. Cayenne.
Type. Female in spirit. B. MI. no. 5. 1. 8. 7. Presented by W. Barnes, Esq.

This little species is evidently a member of the 11. tropidurhynchus group, but may be distinguished by its short fur and the peculiarly swollen shape of its brain-case. Specimens of the true M. obscurus were also obtained by Mr. Barnes at the same time, and are at once recognizable by their very much larger size (forearm $39-10 \mathrm{~mm}$.).

The nearest ally of M. Barnesi is probably Miller's M. pygmeeus* from the Island of Curaça, but this has a brain-case breadth of only 8 mm ., which indicates a very differently shaped skull.

Conepatus tropicalis trichurus, subsp.n.
Apparently very similar to the Mexican C. tropicalis, Merriam, but with decidedly longer tail, whose black is

- P. Biol. Soc. Wash. xiii. p. 162 (1900).

Ann. \& Mag. N. Hist. Ser. 7. Vol.xv,
restricted to a shorter area at the base. Dorsal white streaks barely extending on to the loins (about 280 mm . from commencement on crown), not "to hips." Brush at end of tail very thick, the hairs attaining 110 mm . in lengtl. Fur of back coarse, sparse, not very long (hairs about $30-35 \mathrm{~mm}$. in length), less mixed with wool-hairs than in C. mapurito.

Skull of about the same size as in tropicalis, smaller than in mapurito.

Dimensions of the type (measured in the flesh) :-
Head and body 417 mm . ; tail (vertebre) 170 ; hind foot, s. u. 67, c. u. 74 .

Skull: basal length 69; zygomatic breadth 465 ; mastoid breadth 405 ; palate length 32.7 ; length of upper molar on outer side $9 \cdot 3$.

Hab. Panama and Costa Rica. Type from Boquete, Chiriqui. Alt. 4000 ft.

Type. Male. B.MI. no. 4.7.6.5. Collected 5th March, 1904 , by Mr. H. J. Watson. Five specimens examined.

This skunk has hitherto been referred to C. mapurito, Gm., but the recent acquisition of a second specimen representing that form shows that the Central-American animal is distinct, biing smaller, and having a shorter bushier tail, on which the black extends for a shorter distance at the base. It may also be noted, though probably an accident of preparation, that both our specimens of $C$. mapurito have the dorsal light colour of a dull creamy tone, while in five specimens of the Central-American animal it is really white.

## Nectomys dimidiatus, sp. n.

A diminutive species with the glossy fur of the typical S.-American members of the genus.

Size immensely less than in any hitherto known member of the typical glossy-furred Nectomys, rather smaller even than in $N$. esmeraldarum, the smallest of the fluffy-furred species. Fur obviously modified for an aquatic life, close and glossy, with a thick velvety underfur; hairs of back about 6 mm . in length. General colour of back rather lighter than "clove-brown," the sides becoming more "bistre." A dull buffy line edging the dark colour on the flanks, and ruming down the imer side of the hind limbs. Belly dull clay-colour, deadened by the slaty bases of the hairs showing through. Outer side of arms greyish brown. Upper surface of hands and feet dull white. 'lail of medium length, finely scaled, 15 rings to the centimetre, slaty greyish above, dull white below.

Skull, in correlation with its smaller size, much more lightly built than in ordinary Nectomys; supraorbital ridges little developed, the brain-case broad, smooth, and rounded. Zygomata widely and evenly spread. Nasals not markedly narrowed behind. Palatal foramina much larger than in any other species, narrowed in front, widely open and rounded behind, where they extend to the level of the front edge of $m^{1}$.

Molars much worn in the type, but apparently with the complicated structure of those of true Nectomys, with which their shape and general proportions agree.

Dimensions of the type (measured in the flesh):-
Head and body 125 mm . ; tail 115 ; hind foot, s. u. 26 , c. u. 28 ; ear 13.

Skull: greatest length 30 ; basilar length $23 \cdot 4$; zygomatic breadth 17 ; masals $11 \cdot 2 \times 3 \cdot 2$; interorbital breadth $4 \cdot 8$; breadth of brain-case 13 ; palate length $12 \cdot 8$; diastema $7 \cdot 6$; palatal foramina $5 \cdot 7 \times 2.3$; length of upper molar series 4.4 .

Hab. Escondido River, 7 miles below Rama, Nicaragua.
Tigpe. Old male. B.M. no. 5.3.4.2. Collected 5th November, 1904, by Mr. W. G. Palmer.

This remarkable species, not half the bulk of any hitherto known member of the true glossy-furred Nectomys, is the first of the group found in Central America. Allen's Sigmodontomys Alfari and the closely allied Nectomys russulus of Colombia are forms with more Oryzomys-like fur; but their exact generic position is not at present easy to define, owing to want of specimens with unworn teeth. Although the same difficulty exists with the type of $N$. dimidiatus, its general characters are so much like those of typical Nectomys that I have no hesitation in assigning it to that genus, of which it forms the most diminutive member,
"Caught in banana-plantation, on very wet red clay."

## Proechimys Goeldii, sp.n.

Size about as in the ordinary Para species, P. oris, Thos.* Colour of type a dull greyish brown, darker and more rufous on back, greyer and lighter on head and sides. But this colour is probably not that natural to the animal (which is presumably some shade of rufous), but is due to the action of the preservative in which the specimen has been kept. Under surface dull white, not shapply defined laterally. Spines of back feeble, barely exceeding half a millimetre in breadth, about 17-18 mms. in length, with a long slender

[^62]point; greyish basally, black terminally. Fifth him toc, without claw, reaching just to the level of the front of the pad at the base of the third and $f$ urth digits. Mamme 6, two pairs high, up on the sides between the limbs, one pair in the inguinal region.

Skull less ridged than that of $P$. cayennensis, more heavily built than that of $P$. oris, with a broader muzze, the forchead convex mesially, the protile evenly convex to the middle of the brain-case, then strongly declining backwards, supraorbital ridges not strongly developed and not continued backwards past the fronto-parietal suture, the surface of the parietals smooth and undidged. Malars slenderer and less high than in $P$. oris. Palatal foramina short, enling 4 mm . in front of the molars, parallel-sided, the edges produced backwards as two parallel ridges enclosing the area immediately behind the foramina, this area being at a lower level than the rest of the palate; septum comparatively broad. Posterior palatal notch penetrating to the level of the hinder edge of $m^{2}$. Pterygoids narrow, little spatulate. Bullæ of medium development.

Cheek-tecth of normal size and structure, the premolar and last molar each with four, $m^{2}$ and $m^{3}$ each with an indication of five laminæ. In the lower jaw the premolar appears to have five lamine and the molars four each. In $P$. oris the teeth thronghout, upper and lower, have four lamine each. In $P$. cayernensis the upper all have four laminæ, but the lower premolar is as in P. Goeldii.
1)imensions of the type (measured on the spirit-specimen): -

Head and borly 223 mm ; tail (lost) ; hind foot (s. u.) 49 ; ear 20.

Skull: greatest length 56 ; basilar length 40 ; zygomatic breadth 27.5 ; nasals $21 \times 6.5$; interorbital breadth 13 ; mastrid breadth 20.5 ; palate length from henselion 19.3 ; diastema 12.5 ; palatal foramina $5 \times 3$; length of upper cheek-tooth series $9 \cdot 8$.
/lab. Santarem, Lower Amazon.
T!/pe. Adult female. B.ML. no. 5. 1. 25. 6. Presented by Dr. E. A. Goeldi, after whom the species is named.

The members of the genus Proechimys being only distinguishable by their cranial characters, I have ventured to describe this spiny rat in spite of its apparent discoloration and the tailless condition of the type. The skull is readily distinguishable from that of both $P$. oris and the Guianan species $P$. cayennensis by its peculiar palatal foramina, even it the differences in the number of the molar lamine prove to disappear on the examination of further specimens.

## Agouti sierre, sp. n.

Size comparatively small. Fur long and thick, as in A. Taczancwskii *. General colour about as in that animal, dark brown, near "seal-brown," but less purple. White spots large, subequal, not coalesced into lines, disposed, though rather irregularly, in three rows, of which the most superior approach within an inch of each other on the withers and are about 4 inches apart on the back, where the space is partly filled up by a few extra spots. This Paca is therefore one of the most heavily and evenly spotted of the group. Belly-hairs whitish, washed terminally with pale brown, not sharply demarcated laterally. Top of head blackish brown, without spots; cheeks paler brown, more or less grizzled with whitish; lips and throat dull whitish; a brown chin-spot present. Lars brown, with some whitish hairs at their antesior base. Limbs brown like the sides, their inner surfaces scarcely lighter; upper surface of hands and feet of a reddish brown, quite different to the blackish brown of the general colour, something between "umber" and "Prout's brown"; sole-pads profusely gramulated, except just under the heel. Mammse $1-1=4$.

Skull conspicuously smaller than in paca and Taczanowskit, the surface almost quite smooth (but the type is a female). Zygomatic concavities small. Postpalatal region of skull proportionally short, the postpalatal length less than the distance fiom the back of the palate to the maxillary suture. Teeth large, the length of the molar series conspicuously greater than the maxillary part of the diastema. Bulle very low and small, little inflated, their antero-i, osterior length barely 14 mm ., as compared to $16-17$ in the allied forms.

Dimensions of the type (measured on skin):-
Head and body 650 mm . ; hind foot, s. n. 84 , c. n. 94.
Skull: greatest length 123 ; basilar length 99 ; zygomatic breadth 82 ; nasals $41 \times 225$; interorbital breadth 35 ; tip to tip of postorbital processes 49 ; least breadth above auditory meatus 37.5 ; greatest posterior breadth $47.0 ๊$; or cipital height from basion $2 \mathrm{~s}^{2} \cdot 7$; length of bradened surface of zygoma 64 ; greatest height of zygoma 36 ; zygomatic concavity, measured internally in horizontal plane, $34 \times 10$; diastema 38 ; postpalatal length 38 ; length of npper toothrow (crowns) 28.

Hab. P'edregosa Montañas, Sierra de Merida, Venezuela. Alt. 2000 m.

Typre. Alult female, permanent dentition in place. B.M. יO. 5. 2. 5. 19. ('ollected 24th November, 190t, by S. Briceño. Two specimens. An imperfect specimen from Bogota also apparently the same.
"Eyes blue. Makes a nest underground, with two exits." -S. B.

The Pacas fall into two groups, those of the mountains and those of the plains. The former are comparatively long and thickly haired and darker coloured, and have the sole-parts distinct and profusely granulated; so far as is yet known, they are confined to the mountains of N.W.S. America. On the other hand, the lowland Pacas, ranging from Panama to South Brazil, are more sparsely covered with shorter hair, are paler in colour, brown or rufous, and their foot-pads are smoother, especially posteriorly, and less sharply defined from the general surface of the sole.

T'o the lowland group belong the forms described as paca, Linn., fulvus, F. Cuv., subniger, F. Cuv.*, and virgatus, Bangs, while to the highland series should be referred Taczanowskii, Stolzmann, and the present new form, which may be identified by its small size and very small bullæ. The animal described by Gervais, from the skull only, as sublevis, from Colombia, camot be identified, and the type is no longer to be found in the Paris Museum. It may have been a female of either paca or Taczanowskii, but, no mention being made of its size being specially small, it is not likely to have been the present species.

## Mesomys, Wagn.

At last I am able definitely to identify the genus Nesomys of Wagner, which has been a puzzle to zoologists for half a century. Founded originally on a specimen which had lost its tail, an accident of most common occurrence in the group, tailless specimens of several ether groups have been assigned to it, and all sorts of erroncous conclusions have been published about it on this account. Of late years, as in 1). Allen's paper $\dagger$ on Echimys and Proechimys, it has been looked upon as probably synonymous with the former.

[^63]I now owe to the kindness of Dr. E. A. Goeldi of Para the two spiny rats from Marajo mentioned incidentally in his paper of 1901 on Mesomys ecaudatus * ; and at first I supposed them to represent a new genus, but soon found that they corresponded so closely in all their characters with the original description of Mesomys ecaudatus (except for the presence of a long tail), that they were certainly identical generically, and probably specifically, with Natterer's animal.

Günther's "Echimys fermgineus" $\dagger$ is also assignable to the same genus, and is closely allied to M. ecaudatus.

The following is a short description of the genus, with measurements of one of the Marajo specimens :-

External form as in Proechimys, but the ears short and the feet short and broad, as in Loncheres, the fifth hind toe reaching to the end of the first phalanx of the fourth. Spinous system at a maximum. Tail long, well haired. Cheek-teeth rounded, as in Proechimys, each upper one with five or six transverse laminæ, the lower premolar with five and the lower molars with four oblique laminæ. General form of skull as in Loncheres, the muzzle being similarly short, narrow, and parallel-sided; palatal foramina small; bullæ flatiened.

Exactly as Wagner stated, Mesomys may be said to have the skull, ears, and feet of Loncheres, with the teeth of Proechimys, to which latter it is really no doubt most closely allied. From the structure of its feet it 心 es!mably an arboreal form, like Loncheres, instead of bail terrestrial, like Procchimys. It is true that there are ather more lamine in the upper teeth than is usual in Proechimys, but there is a certain amount of variation in the number of the lamine, even in the same species $\ddagger$, so that this difference does not nullify the strong general resemblance that the teeth of Mesomys have to those of Proechimys.

The following are the dimensions of a Marajo specimen (an adult male, preserved in spirit):-

Head and body 163 mm .; tail 186 ; hind foot (s. u.) 30 ; ear 11.

Skull : greatest length 44 ; basilar length 33 ; zygomatic breadth 22.5 ; nasals $124 \times 5$; interorbital breadth 11 ; mastoid breadth 20 ; palate length 15.3 ; diastema $9 . \pm$; palatal foramina $3 \cdot 5$; length of upper tooth-series $6 \cdot 7$.

- Bol. Mus. Para, iii. p. 170 (1901).
$\dagger$ P. Z. S. 1876, p. 750, pl. kxiv. (animal).

LXXXI.-On a British Specimen of the Great Sea-Perch Epinephelus cemioides, C'apello. By G. A. Bonlenger, F.R.s.

The identification of the huge sea-perches of the genus Epinephelus which have, at rare intervals, been captured on the coast of Cornwall has been a matter of difficulty, as the specimens on which the records are based do not appear to have been preserved. Yarrell, Couch, and Day have confonded several quite distinct fishes in their synonymies of "Serranus gigas." Yarrell's figure certainly represents an Fpine phelus gigas, but it was not taken from a British example, whilst Couch's coloured plate, though incorrect, cleally represents an adult Epinephelus ceneus; so does Day's plate, taken from a young specimen received from the Berlin Muscum. Probally examples of two or three different species of the large Epineplelus of the Mediterrancan and neighbouring parts of the Atlantic have occasionally wandered to our south-western coast, but E. ceneus is the only one which, through Couch's description and figure, may be regarded as properly identified.

Thanks to the generosity of the Directors of Harrods Stores, the British Mnseum has received, in fresh condition, a very fine seaperch measuring 4 ft .2 in . and weighing 70 lbs., whidize bs catught in the middle of May off Looe in Comwail. esenis proves to belong to a species, hitherto unrepresented in the National Collection, which was described and figured by Brito C'apello in 18167 as Serranus cernioides, from the coast of Portugal. Although placed by Day in the synonymy of Serramus gigas, this species differs from it, as well as from $E$. ceneus, in several important characters. The teeth, which Capello described, somewhat vaguely, as in broad bands, differ from those of E. gigas in being in two series on the sides of the lower jaw, as in E. aneus. Whilst in the smaller scates, all ctenoid, and covering nearly the whole maxillary, and in the ridge-like base of the three opercular spines, this species differs from the latter and bears some resemblance to Polyprion americanus or cernium, whence the name cernioides chosen by Capello.

The following description is drawn up from the Looe specimen:-

Teeth in villiform bands in the upper jaw and in front of the lower, with an outer series of larger conical teeth, similar to those on the sides of the lower jaw, where they form two
scries only; a rather small canine tooth on each side, in front of each jaw. Depth of body nearly equal to length of head, one third total length. Snout once and two thirls diameter of eye, which is six and a half times in length of head and once and two thirds in interorbital width; lower jaw projecting; maxillary extending to below the posterior border of the eye, the width of its distal extremity nearly equalling the diameter of the eye; preoperculum slightly produced at the angle, which is armed with feebly enlarged serre; suboperculum and interoperculum serrated ; opercular spines strong, proceeding from three distinct ridges, middle spine nearer lower than upper, lower a little further back than upper; opercular flap acutely pointed ; head covered with ctenoid scales, including the maxillary. 14 gill-rakers on lower part of anterior arch, the longest half the diameter of the eye. Dorsal XI 14, originating above base of pectoral; third spine longest, one third length of head, a little shorter than longest soft rays. Anal III 8; second and third spines equal, one fourth length of head, half length of soft rays. Pectoral a little more than half length of head. Ventral shorter, widely separated from vent. Caudal rounded. Scales $145_{60}^{20}$, all with strongly denticulate edge; lateral line 9 .a . Pinkish brown, without any markings, except a very indistinct dark streak from the eye to the angle of the prooperculum ; fins dark purplish bro ${ }^{+{ }^{+1} \text { e base, blackish }}$ at the end, the tips of the pectoral, vrese mortoraudal fins white. Iris pale golden.

Measurements:-
Total length
mm. ..... 1260Greatest depth of body
350Lenarth of head
380Width of head
210Diameter of eve
\%)
Interorbital width ..... 8.
Third Third dorsal spine ..... 120
Elerenth dorsal spine ..... 75
Longest soft ray of dorsal ..... 150
Third anal spine ..... 70
Longest soft ray of anal ..... 140
Length of pectoral ..... 200
" veutral ..... 160
,, caudal ..... 190

The specimen agrees very closely with Capello's figure, and there cannot be the least doubt as to the correctuess of its identification.

## bIBLIOGRAPHICAL NOTICES.

The Founa of British India, including Ceylon and Burma. Published under the authority of the Secretary of State for India in Council. Edited by W. T. Blaspord.-Butterflies. Vol. I. By Lieut.Colonel C. T. Binghas. London: Taylor \& Francis, 1905. Pp. xxii, 511 ; pls. 10.
Extomology has been given a considerable share in this raluable series of works, and we are glad to see the first of three volumes on the important and interesting group of Buttertlies added. There are some large unfinished works on the subject already; but a compact and complete manual, condensing the vast scattered literature, has long been felt as an ever-increasing want, both by collectors at home and residents in India. There is here every facility given for the determination of specimens, by excellent plain and coloured halffigures, good deseriptions, and carefully worked-out keys of families, subfamilies, and genera. Brief descriptions of the earlier stages are also added, when known.

The Indian Fauna is specially interesting in itself : in the south we find occasional affinities with Africa; and along its northern and western frontier it shades gradually into the Western Palearctic Region, the species of Western India haring Mediterranean affinities, and those of the high mountains exhibiting Alpine, aud occasionally wen Subarctic, affinities. (on the other hand, there is comparatively' little resemblance between Indian and Tropical-American forms.

Col. Bingham has adopted six families of butterflies: Nymphalidæ, Nemeobidx, Papilioni, ${ }^{2}$ n. Pieridx, Lycænidx, and Hesperiidie. The butterflies billisize b; c.e first two families are here described, and the Mymail. ese os oded into six subfamilies, Danainar, Satyrince, Acreince, Libyinuter, Morphince, and Nymphatince. Of these, the Acricince are poorly represented by two species only-one belongiog to a genus peculiar to India, and the other representing a very extensive and characteristic group of African species. The Morphince include a number of magnificent species, rivalling those of Tropical America, the subfamily being elsewhere represented only in that region. The Nemeobidx also are poorly represented in the Indian Fauna by twenty species belonging to five genera against hundreds in the American Fauna-our only European representative of the family being the well-known Nemeobius lucina, the only member of its genus, which is also confined to Europe. Tho Danaince are a characteristic Indian and African group, poorly represented in America. One species, Danais chrysippus, common thr ughout India and Africa, occurs in Greece. The Lilytheince form a small family, represented in most parts of the world, but generally ly only one or two pecies in each country; five, including the south-Suropean Libyther celtis, are included by Col. Bingham in the Indian Fauna. Oi the more familiar subfamilies Sutyrince and Nymphetince, several characteristic European genera are represented in India, and occasionally we find the same or closely allied species, including, of course, the cosmopolitan Vanessic curdui.

Colutoguc of the Lepidoptera Phatence in the British Nusemm. Volume V. Catrologue of the Noctuide in the Collection of the British Museum. By Sir George F. Hampson, Bart. Xro. London : Published by Order of the Trustecs, 1905. Pp. xvi, 634 ; pls. lxxviii.-xcr. (coloured) and text-figures (plain) 172.
The fifth of Sir George Hampon's bienmial volumes contains the classification of the Hadenine, the second of the subfamilies into which the author divides the great family Noctuide. The Noctuidx were commenced in vol. iv., which contained about 1200 species of Agrotine ; the Hadenince are somewhat less numerous, 946 species belonging to 78 genera being described in rol. 5 . The genus Hadena itsolf is restricted to the small group called Newria by Guenée, Noctua reticulata, Vill. ( $=$ saponarice, Esp. $)$, being chosen as the type, because it is the first species included by Schrank under Hadena. The classification of the Noctuidre has altered very much of late years, and Sir George includes many genera formerly placed in separate sections, such as Leucania, Ochs., in the Hadeninæ. Sereral genera, such as Polia, Walk., are given a very wide extension, no less than 216 species being described under Polia. In such a case it is safe to predict that the genus will probably be subdivided later on. The arrangement of the present volume is similar to those which hare preceded it, and Mr. Horace Knight's plates are deserring of high praise.

## MISCELLANEOUS.

On a Modification of the Tentacular Apparatus in certain Species
of Madrepora. By Ahmand Kremp.

A ccriocs arrangement presented by a species of the genus Matiopora (11. Durvillei) was noticed by Fowler in 1866. I have found it in three species of the same genus from the Gulf of Tadjoura. Not one of these three forms appears to me to be capable of identification with that which formed the subject of Fowler's inrestigations.

I note that it is a question of a certain dimorphism affecting a third of the colony examined, and consisting, according to this observer, in a marked hypertrophy of the endodermic epithelium of the upper part of six macrenteric mesenteries of the animal. The formation is traversed in its whole length by a sagittal $U$-shaped canal on the ectodermic walls, terminating in the pharynx in two distinct superposed orifices.

My observations have led me to an altogether different interpretation of the morphological value of these prolongations and of their U-shaped canal. Contrary to all appearance, they do not belong to the mesenteries; they only prolong these superiorly: they are in effect tentacles deformed by important modifications. As for tho ectodermic canal which they contain in their median plane, it represents a portion of the buccal dise which a fusion of two tentacles
has converted into a tunnel and buried in the depths of the body of the thus transformed polypo. The following are the facts which have led me to these conclusions.

The determination of the analogies which exist between the tissue of the voluminous entodermic enlaryements of Madrepora and that of the organ of which I have established the homology with a tentacle in certain Oculinime *-analogies which bear not only on the structure of the cellular elements, but also on the very special histochemical reactions of their conteuts-has from the very outset prepared me to understand the following anatomical con-ditions:-1. The tentacles, so well developed and so easy to observe even when contracted, iu normal individuals, are completely wantiug, at least in their usual form, on the buccal disc of modified individuals, which thus appear to be devoid of them. 乌. The pharynx of these latter, characterized by its very diminutive length, its narrowness, its differentiated ectoderm, is not to be confounded with the irregularly pleated wide and lone funnel which precedes it and on the sertical or oblique walls of which the two orifices of six U -shaped canals open. This funnel is, in effect, nothing more than the invaginated buceal dise of the polype, and, as is known, deprived of visible tentacles. The orifices of each of the canals are therefore not situate in the pharynx, but, and the relation is of eapital importance, on the surface of the buccal dise : they are arranged along one of its radii, one in the neighbourhood of the mouth, the other on the marginal border. 3. I have been able to observe an individual which presented only one U -shaped canal-organ, that of one of the left directing partitions; all its other partitions were normal.

The animal was adult, prorided with six endocoles and six ectococles, and should have possessed twelve tentacles. An examination of its buccal dise shows (a) that it had but ten ; (b) that the two vacant places, very clearly marked in the crown of tentacles and representing the two missing elements, corresponded precisely, ono with the directive endocole, of which the left mesentery was the only one modified, the other with its left ectococle.

Collating these facts, one may deduce from them particularly :-

1. That there is a constant correlation between the presence of the U -shaped canal-organ in an individual and the apparent absence of tentacles on its buceal dise.
2. That the correlation is particularly manifest in the very clear case in which only a single organ is found in the individual, the case in which the two missing tentacles are those of the endoccele and ectoceele which it occupies.
3. That the plane in which the $U$-shaped canal with its two orifices is contained coincides with the plane of separation of two neighbouring tentacles.

I am now in a position to demonstrate how the transformations which give rise to the arrangement under consideration in certain

[^64]indiriduals arise, solely at the expense of the oral disc and the tentacular apparatus by fusion of its elements in pairs.

If we imagine tro contiguous tentacles in a state of semiexpansion; owing to their capitate form they come into slight contact by their superior extremities and so define, between their opposed faces and the portion of the buceal dise intercepted between their two bases, a gutter, open interiorly on the side of the mouth, exteriorly on the side of the margin of the tentacular disc. If this arrangement be fixed ly, so to speak, soldering up, the junction of the two surfaces which are in temporary contact, the gutter aforesaid becomes a canal, which is at once recognizable as the $\mathbf{U}$-shaped canal.

It is situate in au intertentacular plane, its two orifices open on the oral disc, one on the outer side, the other on the inner of the crown of tentacles; lastly, the epithelial covering of its bore is strictly ectodermic.

Returning to what has been described as the soldering together of two tentacles, if we conceive it to be accompanied by the absorption of the two ectodermic surfaces along the line of which it has taken place, it will in reality be effected through the intermediary of their mesogleal lamella. We also nute at the same time that these two latter, fused into one, appear to continue, above the $\mathbf{U}$ shaped canal, the single mesogleal lamellia of the subjacent mesentery: Now if we remove the special histological characters (nematocyst, nervous system) from what is left of the ectoderm of the tentacles, and give, on the other hand, to the cells of their endoderm the large size which is known to be the case, we have completed the synthesis of a U-shaped organ without haring supplied the normal polype with any elements other than those which we intended to employ.

All that now remains is to make the absence of the $\mathbf{U}$-shaped canal-organ on the two partitions of the directing dorsal endocole agree with the apparent disposition of its tentacle. This latter, not having experienced the fate of its neighbours, ought to be recoverable.

Its non-existence is, in fact, more apparent than real. A study of sections has enabled me to discorer its presence in the gastrovascular carity with ease. Inraginated in its endocoele, with its short axial cetodermic canal opening on the buccal disc and its endoderm with its voluminous cells, it is in every sense comparable to its homologue (dorsal tentacle) in the Oculininar. It is thas the totality of the elements of the tentacular apparatus that the change affeets in Madrepora, while in Pecilopora it affects but a small part ( $\frac{1}{4}$ ), and in Serictopora and Stylophora $\frac{1}{T-}$.

The presence of like formations in creatures exhibiting such differences of structure as the Oculininac and the Madreporine, a presence which renders their existence possible in all the Hexacorallids under aspects which may otherwise vary hetween one group and the other-the considerable development which they assume in those individuals in which they are present,-causes one to suspect that they must play an important roile in the physiology of these animals. -Comptes Rentus, tome exxxviii. no. 24, pp. 1519)-1521 (13th June, 1904).

## INDEX то VOL. XV.

Acara, revision of the genus, 330 ; new species of, 337 .

- subocularis, note on, 557.

Acaropsis, note on the grenus, 345 .
Actenuchroma, new species of, 166.

Actumnus, new species of, 260 .
Adrapsa, new species of, $162,501$.

Huechysaria, characters of the division, 481.
Hyaleucerea, new species of, 431, 466.

Hyantiaria, characters of the division, 478.
Hycanus, characters of the new grenus, 545.
Hymenoptera, new, 200, 218, 415, 467, 521 .
Hypætra, new species of, 159.
Hypena, new species of, 163.
Hypocladia, new species of, 461.
lconaxiopsis, new species of, 240.
Ideobisium, new species of, 131.
Ideoroncus, new species of, 127.
Ihering, R. von, on new species of Plecostomus, 558.
Ilema, new species of, 433.
Illice, new species of, 436.
Imms, A. D., on a marine Pseudoscorpion from the Isle of Man, 231.

Isanthrene, new species of, 427.
Ischnocampa, new species of, 466 .
Ixoides, characters of the new gemus, 255.

Ixylasia, new species of, 462.
Juncoptilum, characters of the new genus, 5 อ̄.
Kamalata, new species of, 308 .

Khimbya, characters of the new gemus, 307 .
Kirby, W. F., on Neuroptera Olonata from Salisbury, 190 ; on Odonata from Ceylon, 270; on a new species of Palophus, 275.
Krempf, A., on the tentacular apparatus in certain species of Madrepora, 595.
Labanda, new species of, 156.
Lagena, new species of, 349 .
Lagochilus, new species of, 93.
Lahugada, characters of the new genus, 304.
Laophontina, characters of the new genus, 292.
Lepidoptera, new, $149,19 \%, 3 \because 4$, $372,425,460,495,540$.
Lepidotrigla, new species of, $2 \geqslant$.
Leptognathus, new species of, 561.
Lethama, characters of the new genus, 307.
Leucania, new species of, 196, 324 .
Lewis, G., on new species of Histeridæ, 301.
Lioderma, new species of, $30 \%$.
Liophis, new species of, 455 .
Lithodes Agassizii, note on, 243.
Lobeza, new species of, 542 .
Lophiomys, new species of, 80 .
Loxophlebia, new species of, 428 .
Luciogobius, new species of, 23 .
Lutra capensis, new subspecies of, 78.
Lycophotia, new species of, 372, 457.

Lydekker, R., on the Bonin Island sambar, 391.
Lygosoma, new species of, 208.
Ly'toceratidæ, ou certain genera and species of, 424.
MacGilchrist, Capt. A. C., on Decapod Crustacea from the Indian seas, 233 ; on a new genus of Teleostean fish allied to Chiasmodus, 268 .
M'Intosh, Prof., on the Palolo, 33 ; on Goniadidæ, Glyceridæ, and Aricidæ, 36 ; on Hemipodus magellanicus, 57.
Madrepora, on the tentacular apparatus in certain species of, 590.
Mrenas, new species of, 446 .
Majeorona, characters of the new genus, 318 .
Major, C. I. Forsyth, on the rffinities of the Orkney role, 323 ; on Emropean species of Pitymys, 008. Ann. \& Mag. N. Hist. Ser. 7. Vol. xv.

Maliatha, new speries of. 1int.
Mamestra, new species of, 372.
Mammals, new, 70, 77, 329, 387 , 391, 487, 505, 515, 584.
Marcusenius, new species of, 457.
Marshall, G. A. K., on the SouthAfrican species of Cossonus, $39 \%$.
Matacembelus, new species of, 459.
Mana, characters of the new genus, til.
Medacina, new species of, 503.
Meimuna, characters of the new genu:, 67.
Melastrota, chamaters of the new grenus, 439.
Melissodes, new species of, 52l.
Nerayisa, new species of, 541 .
Mesocheres, characters of the new genus, 297 .
Mesmys, note on the genus, 590 .
Mesothen, new species of, 460 .
Metachrostis, new species of, 500 .
Metaglymma, new species of, 543.
Metarctia, new species of, 426 .
Metopodontus, new species of, 375.
Metoxanthia, new species of, 467 .
Microhyle, characters of the new genus, 437.
Micromys, new species of, 491.
Microtus, on the European species of, 508 ; new species of, 515 .
-orcadensis, on the affinities of, 823.

Miranha, chaacters of the new genus, 381 .
Nisthotus, characters of the new genus, 192.
Morannia, new epecies of, 385.
Alcramiaria, definition of the divivion, 385.
Monera wogura, new subspecies of, 487.

Mollusca, new, 83, 91, 360.
Molossus, new species of, 584.
Monads, on the heterogenetic origin of, 210.
Morrisonia, new species of, 452.
Munidonsis, new species of, 217 .
Nuricella, new species of, 5.53 .
Nimagma, new species of, $\mathbf{1 5 6}$.
Nannacara, characters of the new genus, 344.
Neacerea, new species of, 463.
Nectomys, new species of, 586 .
Neeressa, characters of the new genus, 426 .
Nemachilus, new species of, 187, 301.

Neomys fodiens, new subspecies of $5,07$.
Nephelistis, new species of, 374.
Neritos, new species of, 444.
Neuroptera, new, 190, 273.
Newton, E. T., on a specimen of Fayolia, 326; on an ossiferous cavern at Hue-Grange, 327.
Newton, R. B., on Locene shells from Nigerit, 83.
Noctuidæ, new South-American, 372.
Nola, new species of, 432 .
Norman, Camon A. M., on new Copepoda from Devon and Cornwall, 284 ; on the Natural History of E. Finmark, 348 .
Nothopsis, new species of, 453.
Notogonia, new species of, 224 .
Obisium maritimum in the Isle of Man, on the occurrence of, 231.
Odорюа, new species of, 380.
Ollanta, characters of the new genus, 313.

Onychothemis, new species of, 277.
Ophichthys, new species of, 17.
Opisthostoma, new species of, 360.
Opsaroa, characters of the new genus, 437.

Orapa, characters of the rew genus, 480.

- Ordnance Surrey of the Peninsula of Sinai, note on, 520 .
Orellana, characters of the new genus, 381.

Orthoptera, new, 279.
Pacarina, characters of the new genus, 314.
lalolo, on the, 33 .
Palophus, new species of, 279 .
Palpifer, new species of, 152 .
Panopra, new species of, 88 .
Parasa, new species of, 151.
Parashada, characters of the new genus, 43:3.
Parastenhelia, new species of, 289.
Parevia, new species of, $4 \not 43$.
Parexostoma, new species of, 183.
Parvittya, characters of the new genus, 482.
Peltidium, new species of, 296.
Peneus fissurus, note on, 233 .
P'etaurista leucogenys, new subspecies of, 488.
Petropedetes, new species of, 281.
lhrosia, new species of, $433,497$.
Phaulomys, characters of the new subgenus, 493.

Phrydops, characters of the new genus, 453.
Phryganopsis, new species of, 433.
Platylomia, new species of, $6 \overline{5}$.
Plecostomus, new species of, 5.58 .
Pocock, R. I., on the preorbital pit in the skulls of domestic horses and quaggas, 516.
Poliodes, new species of, 375.
Pomponia, new species of, 68 .
Prepiella, new species of, 435.
Primnoisis, new species of, 551.
Proarna, new species of, 311.
Problepsidis, new species of, 150.
Procavia, new species of, 82.
Proctotrypes, new species of, 204 .
Proechimys, new species of, 587.
Prosopis, new species of, 200.
Protocaulon, new species of, 5.54 .
Protoptilum, new species of, 55\%.
Pseudagenia, new species of, 416 .
Pseudapiconoma, new species of, 426.

Pseudorhnmbus, new species of, 25.
Psithyristriaria, definition of the division, 384 .
Itenoplax, new species of, 266.
l'terois, new species of, 20 .
Ptychozoon homalocephalum, new variety of, 30 .
Purana, characters of the new genus, 60.

Pycnogonids, on the classification of the, 405.
Quaggas, on the preorbital pit in the skulls of, 516.
Quesada, claracters of the new genus, 478.
Mana, new species of, 209.
Regan, C. Tate, on fishes from Japan, 17; synopsis of the species of Parexostoma, Chimarhichthys, and Exostoma, 182; on new fishes from Tibet, 185, 300 ; on a new species of Dentex, 325 ; revision of the genera Acara, Nimnacara, Acaropsis, and Astronotus, 329 ; on the systematic arrangement of the genus Arges, 529; on Acara subocularis, Cope, 557.
Reptiles, new, 29, 171, 190, 208, $358,453,561$.
Rhacophorus nigropalmatus, note on, 32.

Rhadinæa, new species of, 454.
Rhinolophus, new species of, 70 .
Khodoneura, new species of, 504.

Rhyuchotal notes, 58, 304, 379, 478.
Rhyparus, new species of, 537 .
Ridewrood, Dr. W. G., on the skull of Gonorhynchus Greyi, 361.
Rivula, new species of, 154.
Rosén, N., on the snakes in the museums of Lund and Malmö, 168.
Salius, new species of, 474 .
Sambar, on the Bonin Island, 391.
Sarcophytum, new species of, 549 .
Sarwda, characters of the new genus, 62.

Schizopygopsis, new species of, 185.
Schizothorax, new species of, 186.
Scirpearella, new species of, 553.
Scoloplos, new species of, 47 .
Scott, Dr. T., on new Copepoda from Devon and Cornwall, 284.
Sena, characters of the new genus, 307.

Sharp, Dr. D., on an overlooked work, 520.
Shelford, R., on a new lizard and a new frog from Borneo, 208.
Simpson, J. J., on a new Cavernularid from Ceylon, 561.
Smith, E. A., on a new species of Opisthostema from North Borneo, 360.

Sorex araneus, new subspecies of, 506.

Soridus, new species of, 206.
Sphecosoma, new species of, 426.
Spongodes, new species of, 549.
Stachyptilum, new species of, 557.
Stenhelia, new species of, 281.
Stenophyllodes, new species of, 499.
Stereomera, characters of the new genus, 534.
Stidzæras, new species of, 467.
Stobbs, J. T., on the marine beds in the coal-measures of North Staffordshire, 518.
Swinhoe, Col. C., on new species of Eastern Heterocera, 149, 495.
Swinnerton, Dr. H. H., on the changes and variations in the position of the pectoral fin, 319 .
Sybacodes lutulenius, note on, 539.
Symphlebomis, characters of the new genus, 425.
Sympodium, new species of, 548.
Synhalonia, new species of, 203.
Tachysphex, new species of, 223.
Talapa, new species of, 161 .
Tamasa, characters of the ner genus. $3 \times 6$.

Tambusa, characters of the newgenus, 205.

Tanna, characters of the new genus, $t 1$.
Terpnusia, new species of, 306.
Tettigadesaria, claracters of the division, 479.
T'eucer, new species of, 429 .
Theclas spuriua and Th ericusa, on the synonyny of, 194 .
Theobald, F. V., on a uew Ficalbia from W. Africa, 199.
Thomas, O., on new African mammals, 77 ; on a new Cricetulus, 822; on new g:ound-squirrels, :387; on new Japauese mammals, 487; on new Neotropical mammals, 58.4.
Thomson, Prof. J. A., on deep-sea Aleyonaria from the Indian Ocean, 547.

Thymedes, characters of the new genus, 584.
Timora, new species of, 450 .
Tmetolophota, new spécies of, 375 .
Trachyboa gularis, new rariety of, 169.

Tretanorhinus, new species of, 171.

Tricheuros, characters of the nem genus, 451.
Trichodesma, new species of, 430 .
Trichopeltarium ovale, note on, 261.
Tridentiger, new species of, 22.
Triepenlus, new species of, 201.
Tympanistes, new species of, 158.
Tympanoterpes, new species of, 313 .
Urolasia, new species of, 462 .
Uroptychus, new species of, 249 .
Vulsella, new species of, 85.
Waterhouse, C. O., on new E. African Coleoptera, 375; on Coleoptera of the family Buprestidæ, 577.
Waters, A. W., on recent Bryozoa in d'Orbigny's collection, 1.
With, C. J., on Chelonethi in the British Museum, 94, 328.
Xanthodes, new species of, 258.
Xerus, new species of, 387.
Zammararia, definition of the division, 380.
Zatrephes, new species of, 440.
Zethes, new species of, 160.
Zia, new species of, 432.
Zoogloea masses, on the development and transformations of, 210 .
Zygouidia, new species of, 273.

[^20]:    type, of 1 ith. a. Andersoni are immature (though apparently full-grown or very nearly full-grown) individuals, as proved by the still not ankylosed epiphyses of the metacarpals and phatanges. This must be borne in mind when comparing their measurements with those of the adult Mh. a. brachygnathus. It will be seeu that, notwithstanding their smaller size (and immature age), the specimens of IRh. a. Andersoni have markedly lirger sliulls and teeth than those of Rh. a. brachyguthes.

[^21]:    * Together with Rh. athiops; but this species, although extremely interesting as the hitherto only known West-African representative of the group, has a more isolate position, differing much more from the two other species than these latter inter se.

[^37]:    * "On the Vole and Shrew of the Orkney Islands," by W'm. Eagle Clarke. With Report by Prof. O. Charnock Bradley, M.B., C.M. (Koprinted from 'The Annals of Scottish Natural History;' Jaumary 1905.)

[^38]:    * Eigenmann and Bray say, "No type was indicated for Acara until Gill in 1858 restricted it by exclusion of species of Astronotus and Cichlasoma to Heckel's Acara crassispinis. But it has since been determined that the Acara crassispinis of Heckel is a synonym of Lobotes ocellatus, Agassiz, which is the type of Astronotus. The name Acara is therefore the exact synonym of Astronotus." This argument appears unsound. After removing from Heckel's qenus the species which belong to Astronotus, Cichlosoma, and Acaropsis, I use Acara for the remainder, regarding Gill's restriction of the name Acara to a species which was already the type of another genus as invalid.

[^39]:    ${ }^{1}$ Heros centralis, Holmberg (Rev. Argent. i. 1891, p. 183), is an insufficiently described species of doubtful position placed by Pellerrin in this genus. It may prove to be a Geophayns of the type of $G$. Balzuni, Perugia. Acara minuta, Hensel (Arch. f. Nat. 1870, p. 71), appears to me to be founded on young examples of Geophagus gymuogenys, Hensel.

[^40]:    * Dr. Steindachner has very kindly informed me that in adult males the caudal is even slightly emarginate.

[^41]:    * Of the four specimens three hare fifteen dorsal spines.

[^42]:    1. ( 136 mm. ) type of the species. 2-4. (113-126 mm.)
[^43]:    * Bellis perennis is confined to quite the southern part of Norway.
    $\dagger$ Scilla nutans is not found in Norway at all.

[^54]:    * V. Fatio, Faune Vert. Suisse, iii. App. pp. vii-ix.-Quite recently (Arch. Sc. Phys. et Nat. (4) xix. pp. 188-198, 1905) Dr. Fatio has made remarks upon Microtus (Pitymys) subteraneus, De Selys, from Switzerland. The specimens from the majority of Swiss localities are somewhat hesitatingly referred to a new subspecies or variety, multiple.: I shall have to take this paper more fully into consideration in a future note, and wish only to mention here that I find myself in disagreement with Dr. Fatio in what he considers to be the cranial characters of typical M. subterrancus in specimens from "France":-"Face supérieure de la boite cranienue subarroudie et assez large en arrière, avec recouvrement plutôt étroit de l'ocipital." This applies well to the members of the duodecincostatus group (in which, however, the $m^{9}$ has invariably three internal angles), whereas typical subterraneus skulls from Belgium, at my disposal, agreeing with the fig. 2 lis, pl. iii. of the 'Micromammalogie,' have precisely the characters assigned to the new subspecies. Unless Dr. Fatio had before him a new, and as yet undescribed form from some part of France, his supposed typical subterranei may be specimens of a species of the duodecimcostatus group in which, for one reason or other, the pattern of the $m^{3}$ cannot be made out.
